Detectors

1.	Introduction	6	Scintillation principles (organic/inorganic)
1.1	Energy loss in matter	6.1	Timing counters
1.2	PID with energy loss	6.2	Tracking fibre detectors
1.3	Energy loss of electrons	6.3	Nobel gases
1.4	Multiple Scattering	6.4	Light collection
2	Ionisation detectors	7	Calorimetry
2.1	MWPC	7.1	Electromagnetic calorimeters
2.2	Gaseous microPattern detectors	7.2	Hadronic calorimeters
2.3	Drift chambers	7.3	Combined calorimetry
2.4	Time Projection Chambers		
3	Electromagnetic radiation	3.3	Particle ID summary
3.1	Cherenkov radiation	8	Brief look into the past: bubble chambers
4	Solid state tracking detectors		
4.1	Strip detectors		
4.2	Pixel detectors		
5	Photon detection - principles		
5.1	PMTs		
5.2	Avalanche diodes and Silicon PM's		

What do we want to determine ?

Goal: measure 4-momentum and spatial position of particles

Methods:

- position sensitive detectors
- deflection in magnetic fields
- absorption in calorimeter
- mass

- Cherenkov radiation,
- time of flight
- transition radiation

- energy loss
- characteristic decays

direction and position of 4-vectors
modulus of $|p|$
energy E
 $e, p, n, \pi, .$ (only well defined mass values can occur)

velocity β

$$\beta = \frac{v}{c} = \frac{p}{E}$$

γ

$$\gamma = \frac{1}{\sqrt{1 - \beta^2}} = \frac{E}{m_0 c^2}$$

β, γ

secondary particles

detection in detector:

- small energy loss $\Delta E \ll E$
- large energy loss $\Delta E \sim E$ (calorimetry)

1 Detection of Particles

Exzellenzcluster Universe

What do we want to determine ?

Electrically charged particles

- Ionisation: charge
- Excitation: scintillation light
- Polarisation: Cherenkov light, transition radiation
- Bremsstrahlung + pair production: electromagnetic shower

Photons

- photo electric effect, Compton scattering: charge
- pair production: charge, 511 keV photons
- pair production + Bremsstrahlung: electromagnetic shower

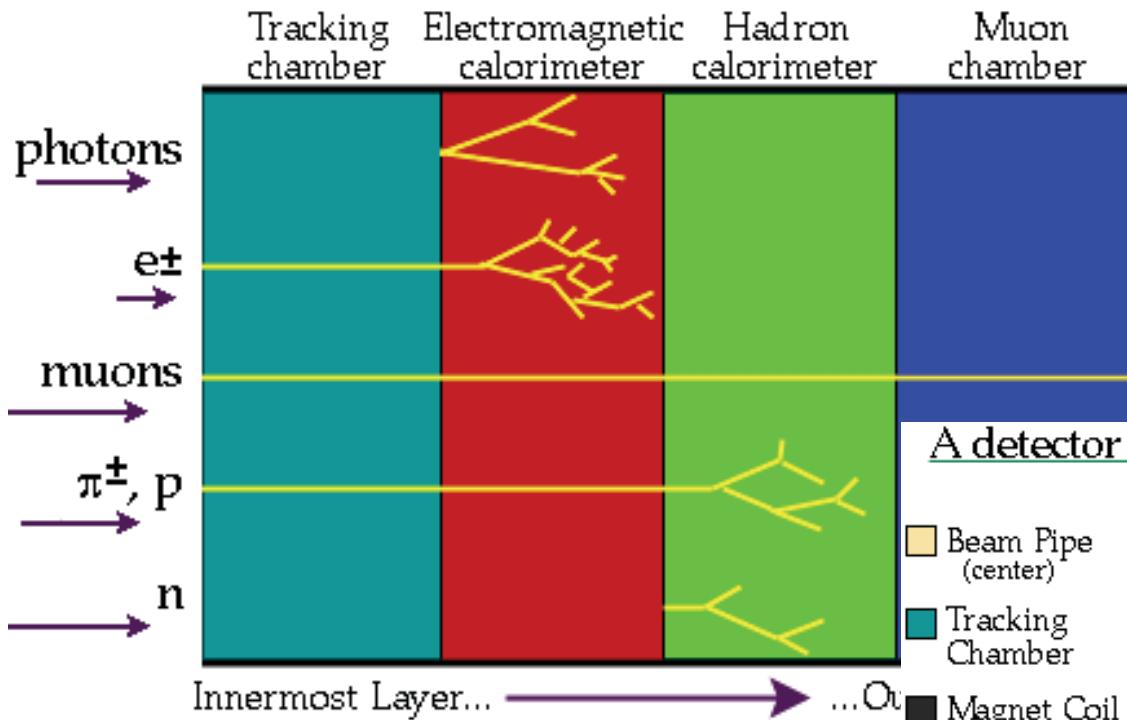

Neutrons

nuclear reactions (n,γ) , (n,α) , (n,p) : detection of decay product
 $n-p$ elastic scattering: detection of recoil protons

Hadrons

Strong interaction: hadronic showers

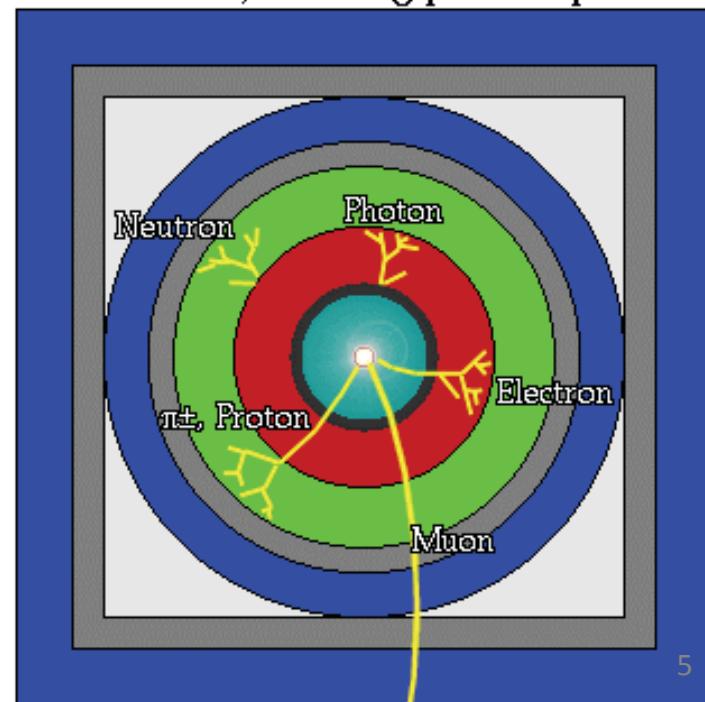

1 Typical Arrangement of a Detector

calorimeter: “shower detector”

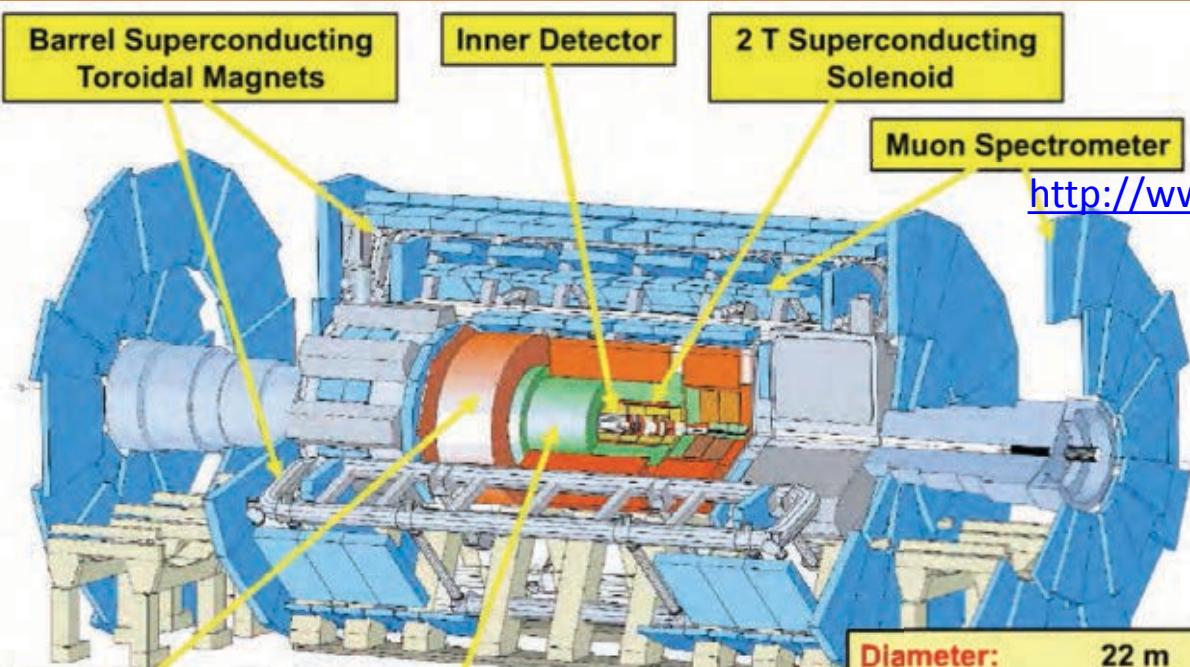

A detector cross-section, showing particle paths

- Beam Pipe (center)
- Tracking Chamber
- Magnet Coil
- E-M Calorimeter
- Hadron Calorimeter
- Magnetized Iron
- Muon Chambers

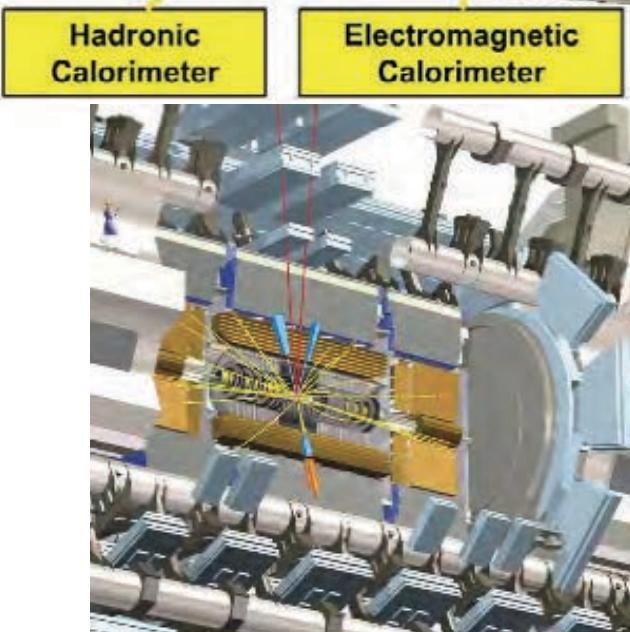

Components of a detector:

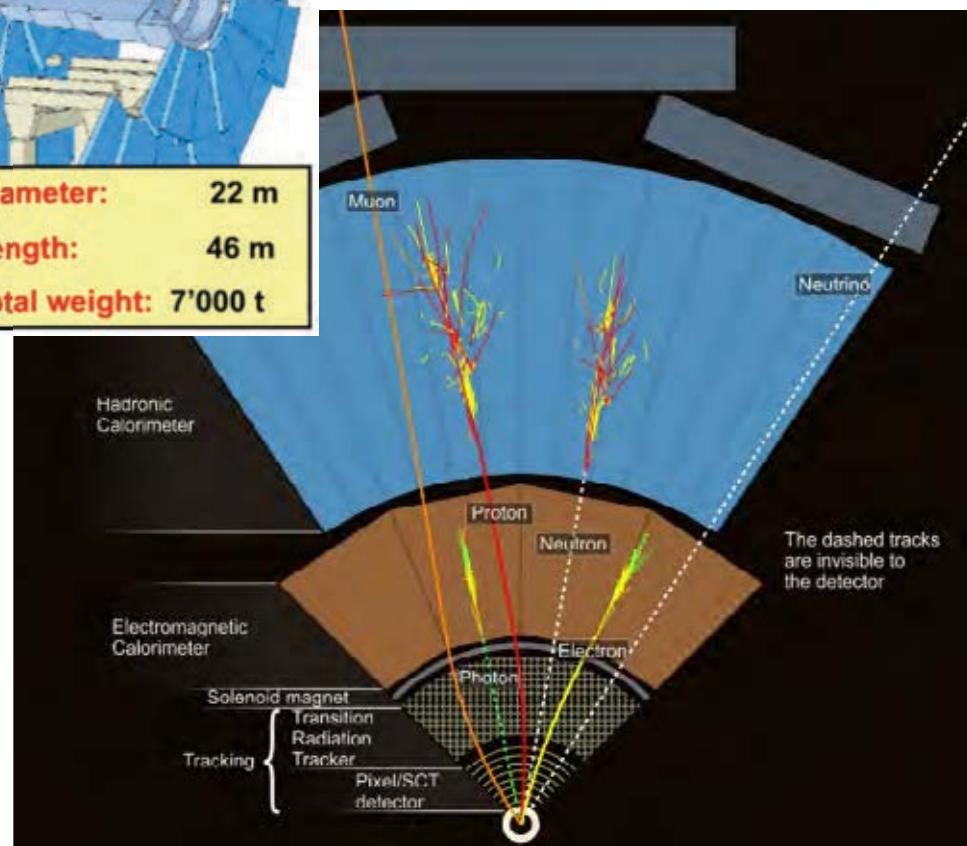

measurement of different aspects:
- trajectory, charge, momentum,
energy, particle species,

more details later

Diameter: 22 m
Length: 46 m
Total weight: 7'000 t

1.1 Energy Loss of Particles in Matter

Exzellenzcluster Universe

Interactions of charged particles with matter:

1. Inelastic collisions with electrons in atomic shell

- energy loss
- excitation or ionisation of atoms
- scattering

2. Elastic collisions

- scattering
- energy loss (mostly negligible as $m \ll M$)
- no excitations

3. Emission of Bremsstrahlung

- Typical for e^+ , e^-

4. Cherenkov radiation, transition radiation in inhomogenous materials

5. Nuclear reactions

1.1 Energy Loss of Particles in Matter

Exzellenzcluster Universe

Example:

relativistic, heavy, charged particles (μ, π, α, p):

almost always scatter inelastically

properties of inelastic collisions :

- statistical
- energy loss fluctuates

number of collisions very large: fluctuations become small

Characteristic quantity: mean energy loss per unit length

$$\left\langle -\frac{dE}{dx} \right\rangle \quad \text{'Stopping-power'}$$

1.1 Energy Loss in Collisions

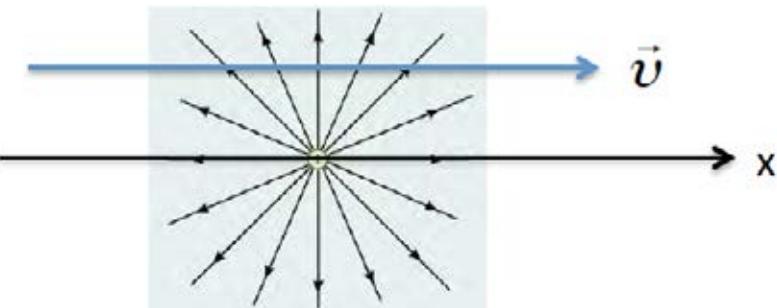

Inelastic collisions with electron cloud of an atom

momentum loss

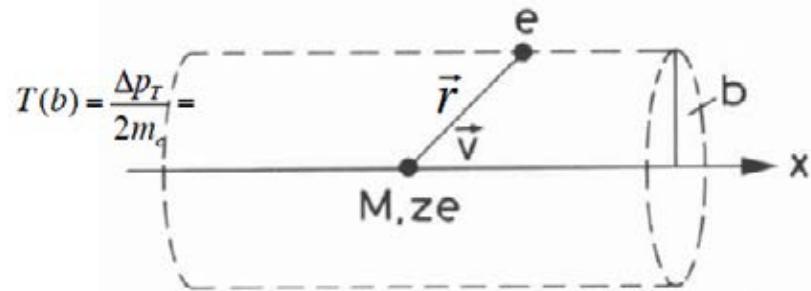

$$\Delta p = \int_{-\infty}^{+\infty} F_{\text{Coulomb}} dt$$

Only transverse forces
horizontal forces cancel

$$F_{c\perp} = F_{\text{Coulomb}} \cdot \frac{b}{|\vec{r}|} = F_{\text{Coulomb}} \frac{b}{\sqrt{x^2 + b^2}}$$

\vec{v} velocity of incoming
particles

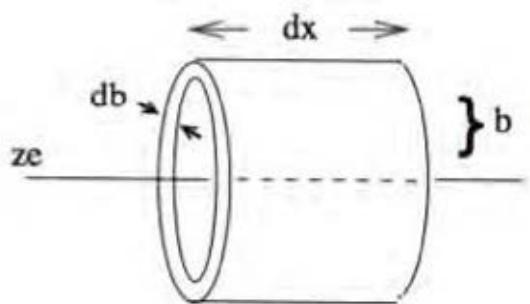

$$\Delta p = \int_{-\infty}^{+\infty} F_{c\perp} dt = \int_{-\infty}^{+\infty} F_{c\perp} \frac{dx}{v} = \frac{2ze^2}{vb}$$

Energy transfer $\Delta E(b)$ on
atomic shell electron

$$\Delta E(b) = \frac{\Delta p^2}{2m_e} = \frac{2z^2e^4}{m_e v^2 b^2}$$

1.1 Energy Loss in Collisions II

Energy loss of incoming particles: how many electrons does the incoming particle see with an impact parameter b ?

probability, to meet an e^- with impact parameter
[$b, d+db$] = number of e^- in volume = $P(b)db$

$$P(b)db = n_e \cdot 2\pi b \cdot db \cdot dx$$

$$n_e = \frac{Z}{A} N_A \rho \equiv \text{number of } e^- \text{ per unit volume}$$

N_A = Avogadro Numero

ρ = density

Z = charge = # e^- pro Atom

A = mass number

$$-dE(b) = \Delta E(b) \cdot 2\pi \cdot n_e \cdot b \cdot db \cdot dx = \frac{4z^2 e^4}{2b^2 v^2 m_e} 2\pi \cdot n_e \cdot b \cdot db \cdot dx = \frac{4\pi n_e z^2 e^4}{v^2 m_e} \frac{db}{b} dx$$

for particles of charge z

integrate over $b_{min} < b < b_{max}$

$$-\frac{dE}{dx} = \frac{4\pi n z^2 e^4}{m_e v^2} \int_{b_{min}}^{b_{max}} \frac{db}{b} = \frac{4\pi n z^2 e^4}{m_e v^2} \ln \frac{b_{max}}{b_{min}}$$

1.1 Energy loss in Collisions III

Exzellenzcluster Universe

Integrate over all impact parameters in the range from b_{min} to b_{max}

- maximum b: momentum transfer must be large enough to separate atomic electron

$$\Delta E(b_{\max}) = \Delta E_{\min} = I = \text{Ionisationsenergie}$$

- minimum b : $\Delta E(b_{\min}) = \Delta E_{\max}$

$$\Delta E_{\max} = \frac{1}{2}mv^2 \left(\frac{4m_e}{m} \right) = \frac{2z^2 e^4}{m_e v^2 b^2}$$

$\frac{1}{2}mv^2$ = energy of incoming particle of mass m

impact parameter:

$$b_{\min} = \frac{ze^2}{m_e v^2}; \quad b_{\max} = \frac{ze^2}{v} \sqrt{\frac{2}{m_e I}}$$

classical formula

$$-\frac{dE}{dx} = \frac{4\pi z^2 c^4}{mv^2} \frac{Z}{A} \cdot N_0 \cdot \ln \sqrt{\frac{2m_e v^2}{I}}$$

Bethe-Bloch Formel:

$$-\frac{dE}{dx} = 4\pi N_0 \frac{Z}{A} \frac{z^2 e^4}{mv^2} \cdot \left[\ln \frac{2m_e v^2}{I} - \ln(1 - \beta^2) - \beta^2 - \frac{c_k}{Z} \right]$$

z: charge of incoming projectile

Z: charge of target nucleus (e.g. Z=6 for carbon)

x: thickness traversed [g/cm²]

N_A/A: number of nuclei/unit volume

I: effective ionisation potential

c_k: correction factor: binding in K-shell

β: v/c

1.1 Energy Loss in Collisions IV

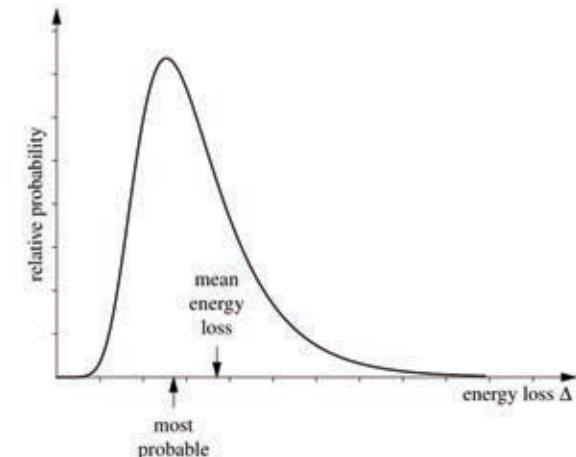

Fluctuation of energy loss

- energy loss is **statistical process**
- specific energy loss (dE/dx) is **sum of many individual processes** → **statistical fluctuations**
 - number of processes
 - energy transfer inn individual process
- energy loss described via **Landau distribution**

$$P(\Delta E - \Delta E_{\text{mp}}) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(\lambda + e^{-\lambda})}$$

$$\lambda = \frac{\Delta E - \Delta E_{\text{mp}}}{\xi} \text{ mit } \xi \text{ as material dependent constant}$$

ΔE_{mp} : most probably value for ΔE

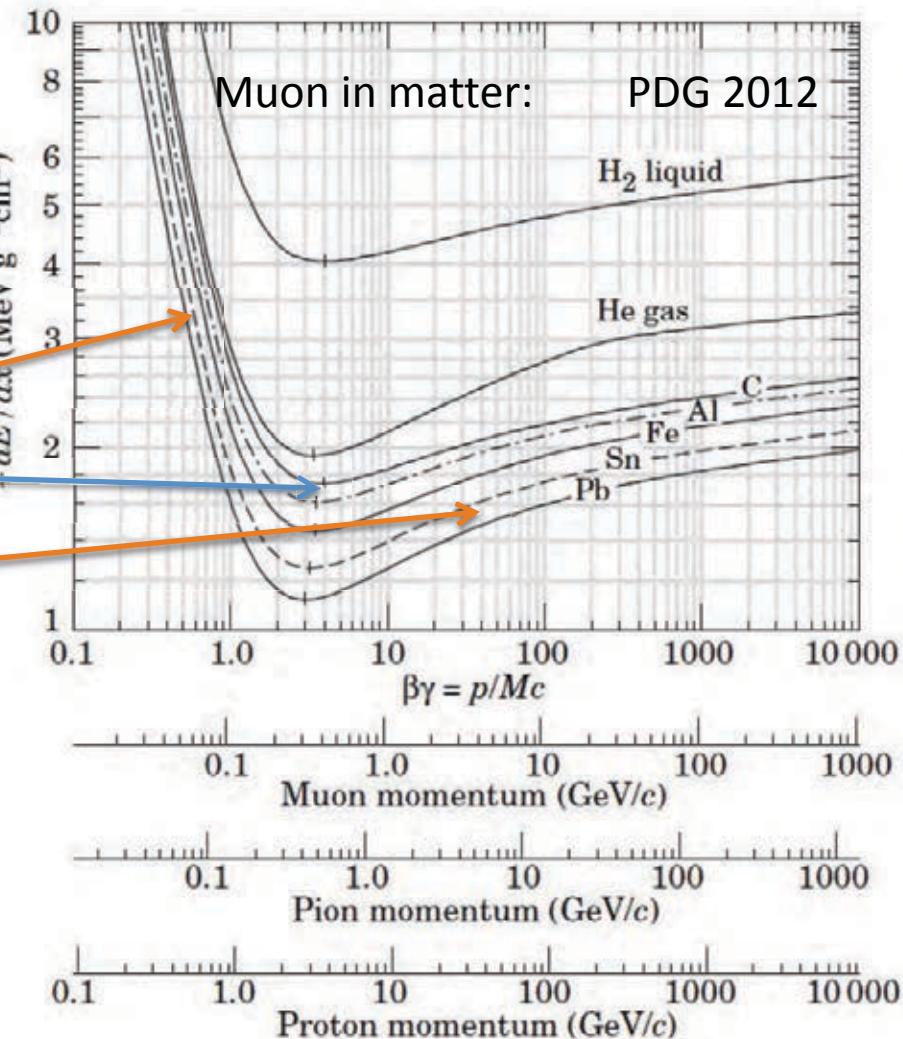

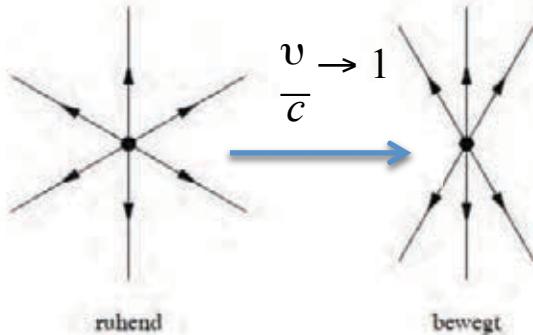

Bsp. Argon: $\xi = 125 \text{ keV}$
 $\Delta x = 1 \text{ cm}$
 $\Delta E_{\text{mp}} = 1.2 \text{ KeV}$
 $\Delta E_{\text{mittel}} = 2.69 \text{ KeV}$

- Thick layers: distribution of dE/dx is gaussian around $(dE/dx)_{\text{Mittel}}$
- Thin layers:
 - large fluctuations of ΔE
 - individual processes with high individual energy loss ΔE contribute to „tail“ of distribution
 - generation of δ -electrons

1.1 Energy loss in collisions VI

Properties:

- Independent of the particle mass
- Speed dependent
- Depending on ionization potential
- **at low energies:** $-\left\langle \frac{dE}{dx} \right\rangle \propto 1/\beta^2$
- **Minimum for** $\beta\gamma \sim 3$
- **at high energies:** $-\left\langle \frac{dE}{dx} \right\rangle \propto \ln \beta^2 \gamma^2$

Transverse electric field amplified due to Lorentz contraction
Increase in range → **relativistic rise**

1.1 Energy Loss in Collisions VII

- (almost) material independent $-\left\langle \frac{dE}{dx} \right\rangle \propto z^2(Z/A) \cdot f(\beta, I)$

- density dependent effect : polarisation of atoms along trajectory if b becomes atomic distance:
→ screening
→ reduction of effective n_e

$$R = \left. \frac{dE}{dx} \right|_{\text{saturation}} / \left. \frac{dE}{dx} \right|_{\text{min}} \quad R = 1.8 \text{ for gases}$$
$$R \text{ ca. } 1.2 \text{ for solids}$$

Material	$dE/dx _{\text{min}} [\text{MeV/cm}]$
plexiglas	2.3
iron	11.65
uranium	20.66
xenon (gas)	$7.3 \cdot 10^{-3}$

1.1 Energy loss of heavy projectiles

Exzellenzcluster Universe

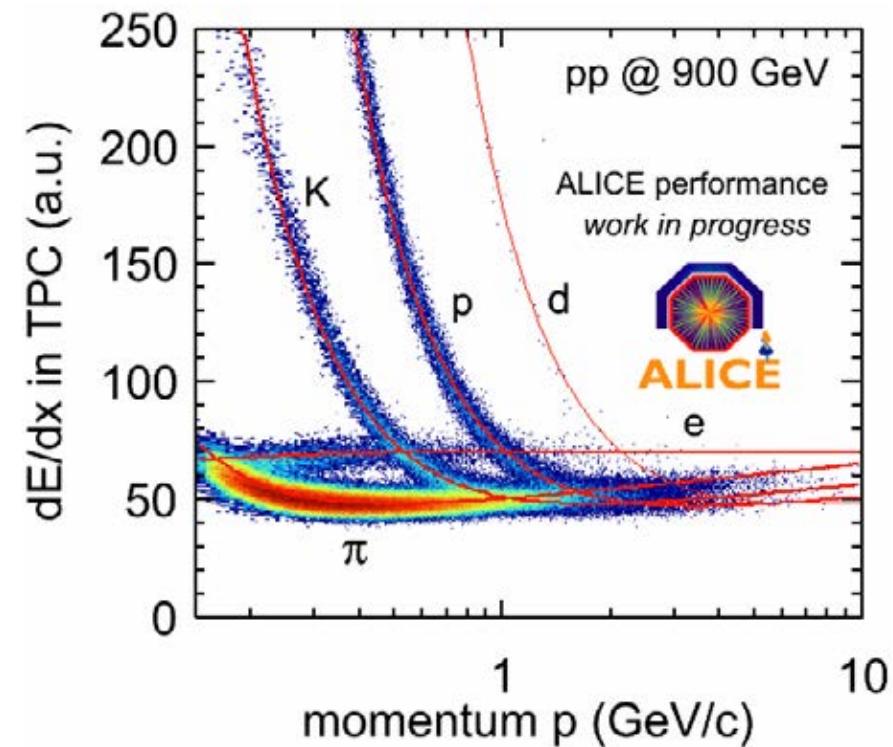

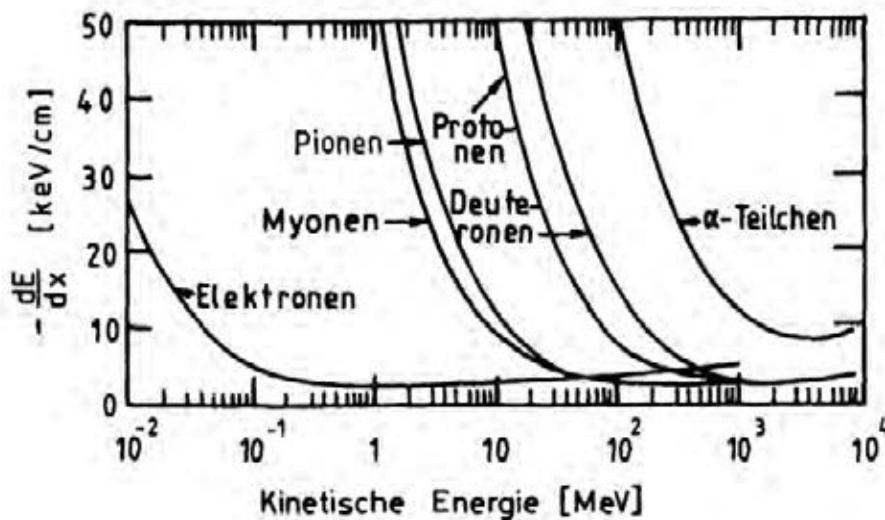

Heavy projectiles make collisions with atomic nuclei

- High energy transfer, greater stopping power
- Breaking of the core/projectile - inelastic collisions → hadronic shower

1.2 Particle ID through Energy Loss

Energy loss for electrons higher: due to $m=m_e$ ΔE_{max} increases

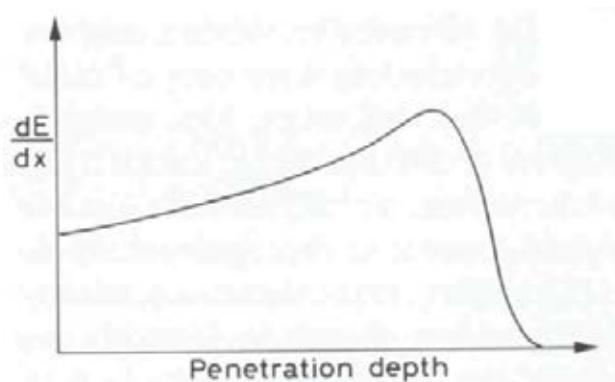

Particle identification by detection of energy loss: determine E and dE/dx of a particle

1.2 Energy loss in the event of collisions VIII

Depth of penetration into matter:

Schematic

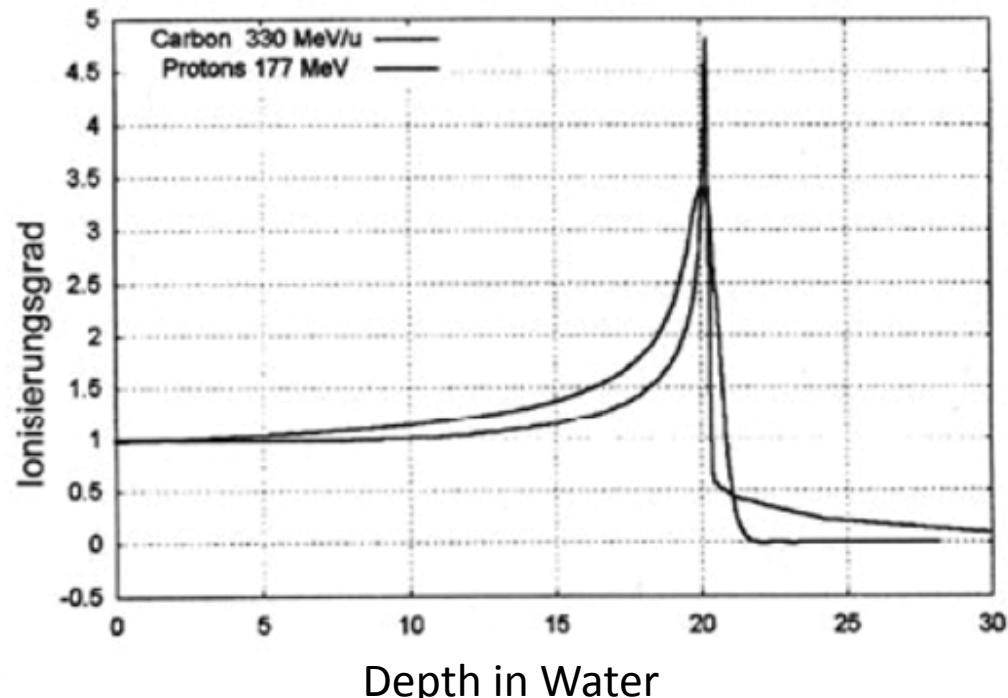

medical applications !

radiation therapy (tumor)

detection of very low energy particles

- integrated energy loss = stopping power
- stopping power increases with decreasing particle energy
- energy deposition is maximal at end of flight path

. . . e.g. medical applications

1.3 Energy Loss of e- and e+

Exzellenzcluster Universe

Energy loss in Materie:

$$\left(-\frac{dE}{dx}\right)_{total} = \left(-\frac{dE}{dx}\right)_{coll} + \left(-\frac{dE}{dx}\right)_{rad}$$

losses through Bremsstrahlung:

$$-\frac{dE}{dx}_{rad} \propto \frac{Z^2}{A} \frac{e^4}{m^2} E_0 z^2$$

$$-\frac{dE}{E} \propto \frac{dx}{X_0} \dots$$

$$E = E_0 e^{-x/X_0}$$

„radiation length“ $X_0 \propto A / Z^2$

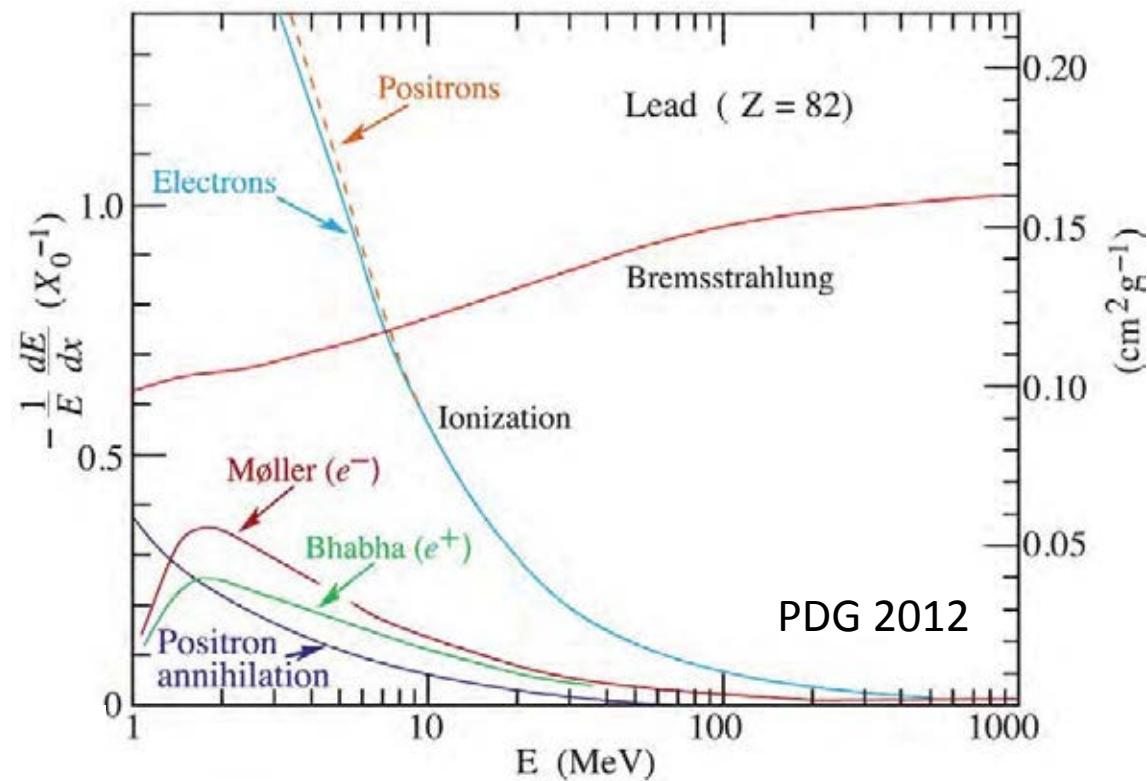

radiation length: Δx for which :

$$\frac{E_0 - \Delta E_{rad}}{E_0} = \frac{E}{E_0} = \frac{1}{e}$$

1.3 Energy Loss of e- and e+

Processes:

1. inelastic collisions with electrons, excitation and ionisation
differences to heavy particles... modification of the Bethe-Bloch formula:
 - recoil
 - spin dependence
2. Bremsstrahlung: Scattering in electric field nucleus and atomic electrons
3. Møller scattering $e^-e^- \rightarrow e^-e^-$
4. Bhabha scattering: $e^-e^+ e^-e^+$
5. e^-e^+ annihilation

1.3 Energy Loss of e- and e+

critical energy:

$$\left(\frac{dE}{dx} \right)_{coll} = \left(\frac{dE}{dx} \right)_{rad}$$

critical energy is material dependent:

$$E_C = \frac{610 \text{ MeV}}{Z + 1.24} \text{ (solid)}$$

$$E_C = \frac{710 \text{ MeV}}{Z + 0.92} \text{ (gaseous medium)}$$

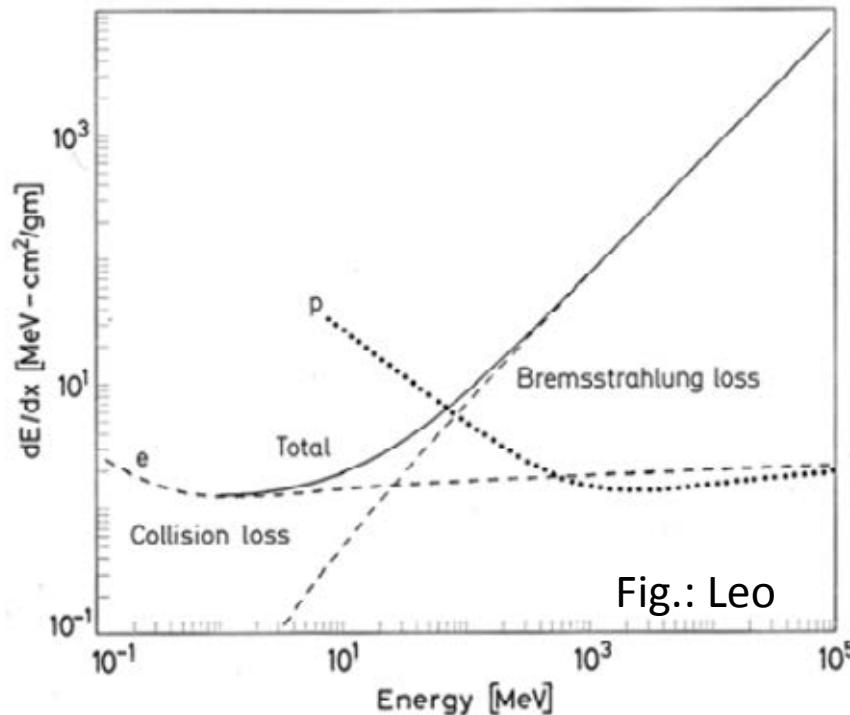

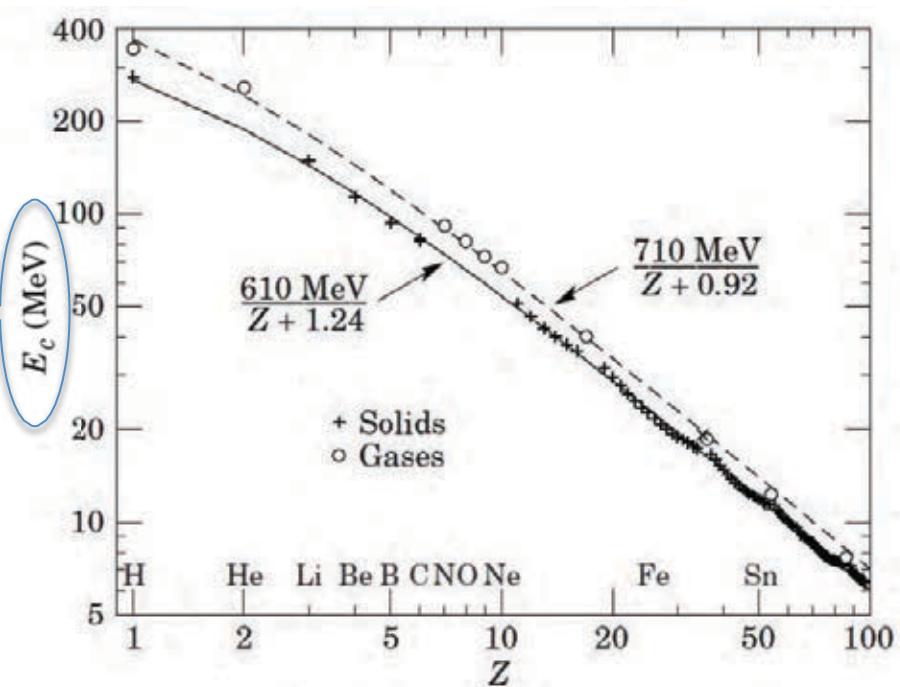

Fig.: Leo

1.3 Energy Loss of e- and e+

critical energy for electrons

... for muons

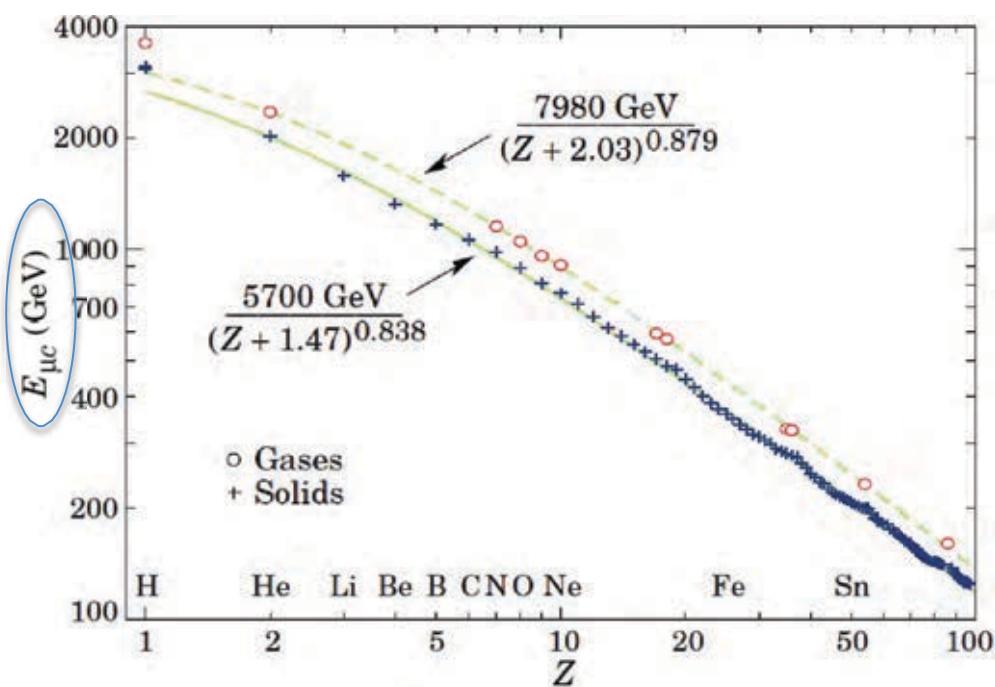

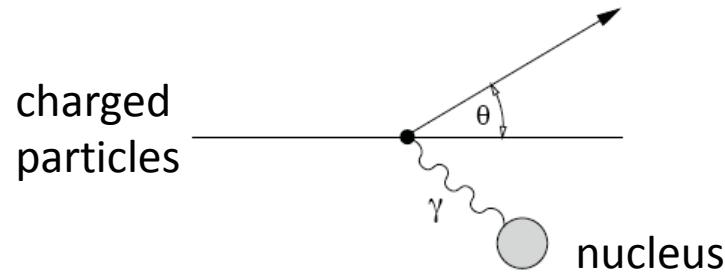

Fig: PDG 2012

1.4 Multiple Scattering

At high energies:

Scattering off nuclear Coulomb potential is dominant:

Rutherford scattering from a nucleus

$$\frac{d\sigma_{\text{Ruth}}}{d\Omega} \sim \frac{1}{\sin^4 \frac{\theta}{2}}$$

many scatterings in matter

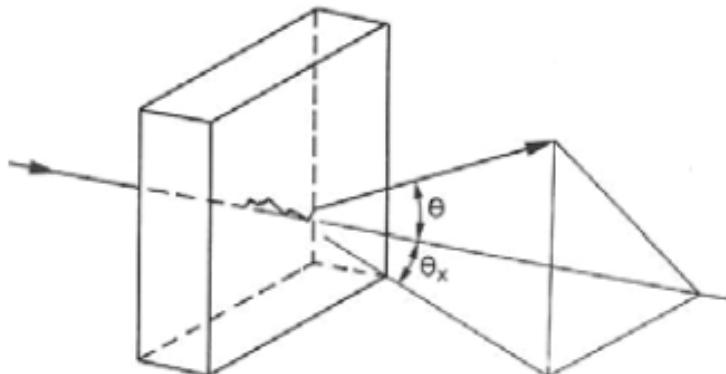

For $m_{\text{Particles}} \ll m_{\text{Kern}} \dots$

change of direction, small energy transfer

Infinitely many scattering centres:

- Gaussian distribution of the scattering angle (Molière Scattering)
- individual scattering events with larger angles

1.4 Multiple Scattering

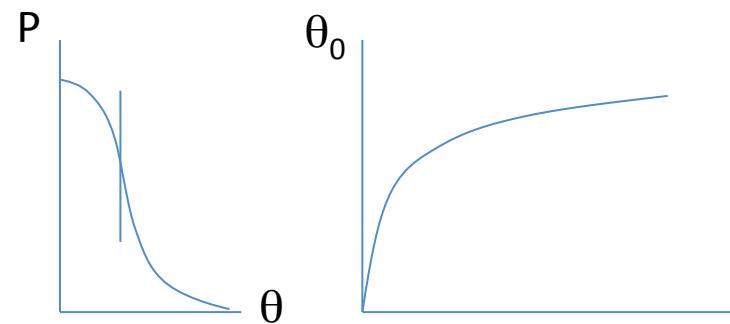

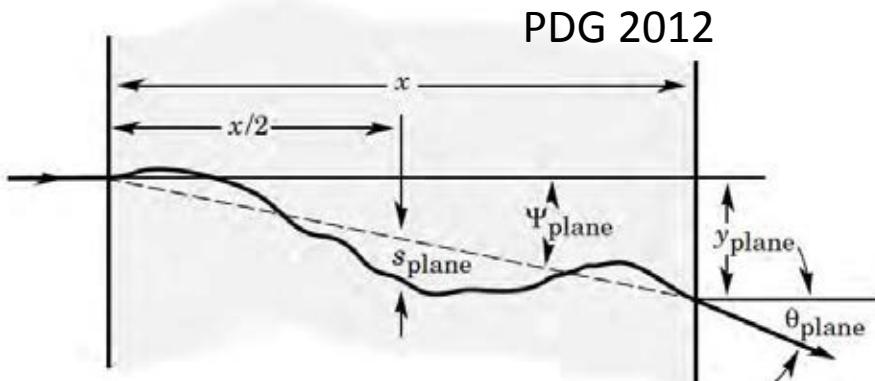

- random path

Probability of exit angle:

$$P(\theta)d\theta = \frac{1}{\sqrt{2\pi}\theta_0} \exp\left(-\frac{\theta^2}{2\theta_0^2}\right) d\theta$$

θ_0 ... width of Gaussian
mean broadening

$$\theta_0 = \frac{13.6 \text{ MeV}}{\beta cp} z \sqrt{\frac{L}{X_0}} \left[1 + 0.038 \ln\left(\frac{x}{X_0}\right) \right]$$

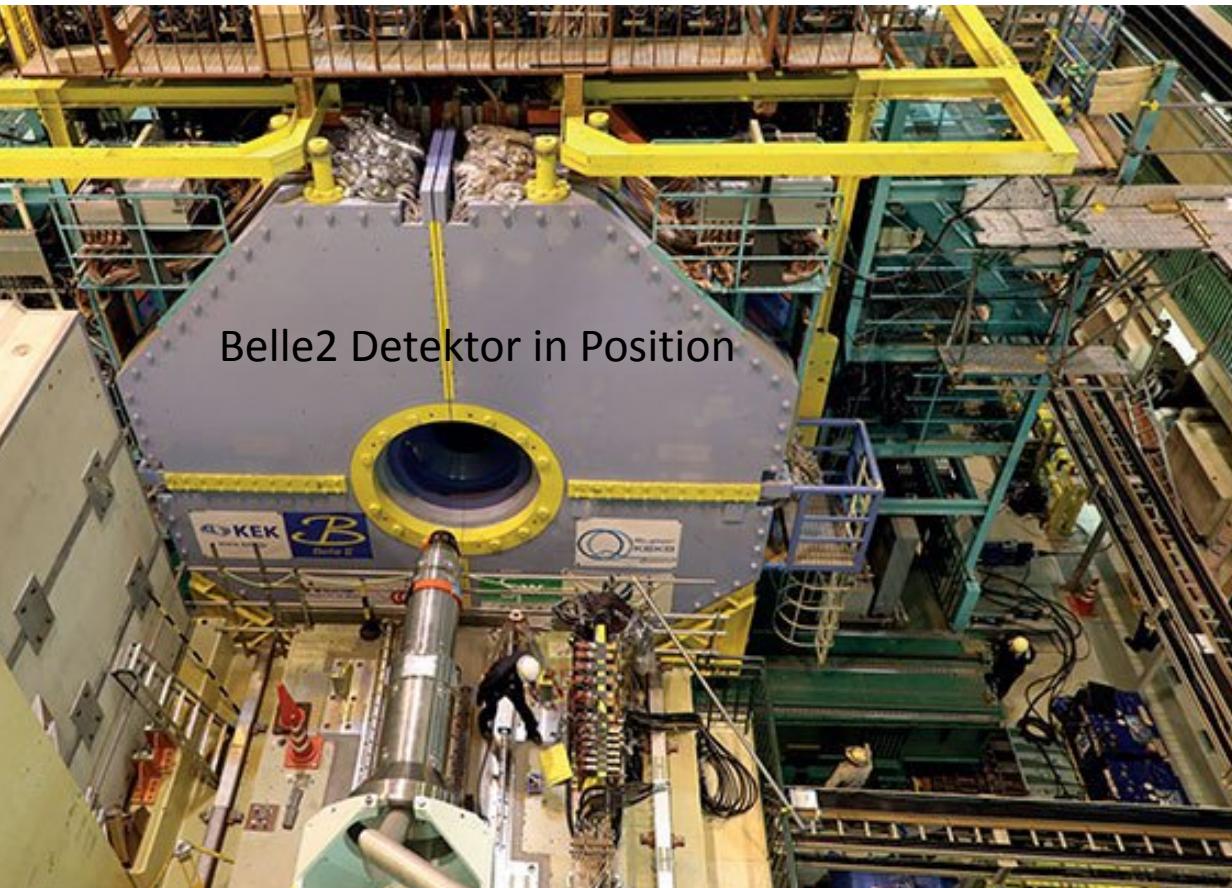

Example: 1 GeV/c proton in 1m Argon: $\theta_0 = 0.03^\circ$ (Atlas) θ_0

Particle Detectors

Stephan Paul
TU-München
stephan.paul@ph.tum.de

2. Ionization Detection

Principle:

- Ionising radiation generates electrons and holes (ions)
- Collecting electrons and holes in the detector

Detector material:

-Gas:

Fast collection of e^- and ions. Detector gases: Ar, Ne, ...

- Liquid:

High density, e.g. liquid Ar, Xe,

- Solids:

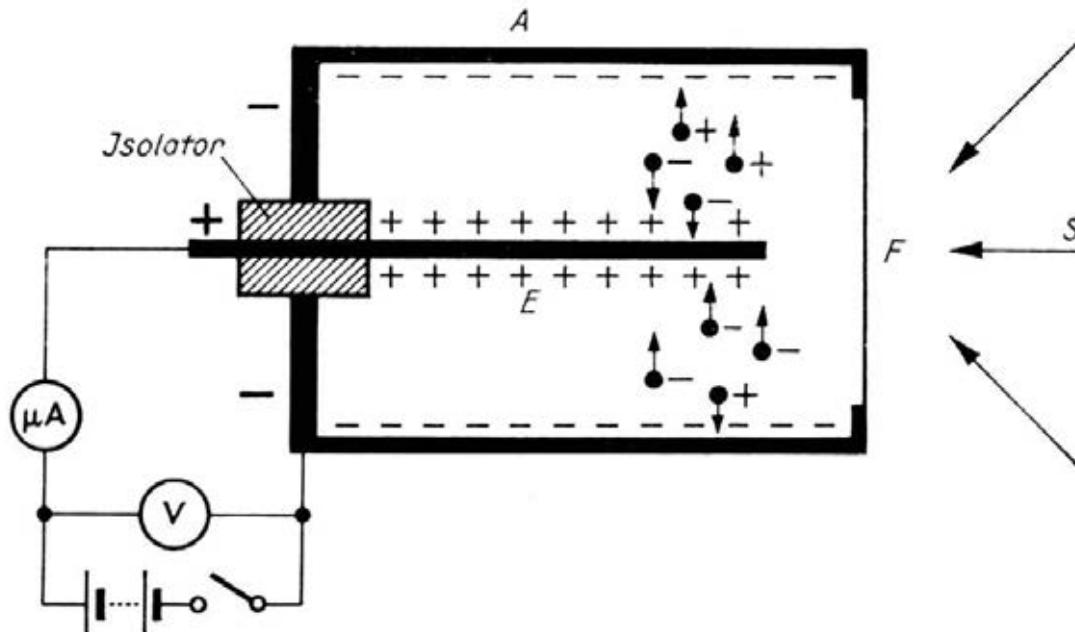

High density, mechanically stable, e.g. semiconductor (Si, Ge, . . .)

Experiment:

- Vessel with electrodes and entrance window
- Filled with active medium for interaction with ionising radiation (e^- - hole(ion) pairs)
- Electrical field between electrodes for collecting the charge carriers:
 - e^- and holes (ions) collected separately
 - Drift, diffusion
 - Signal = 'current' from collected batches in Cathode/Anode

2. Ionization Detection

Ionization chamber:

- **Generation of charge carriers in electric field E**
- **Historical:**
V.Hess could only detect the change in voltage
- **current detection**

Prinzip der Ionisationskammer.

F Eintrittsfenster;	A Abschirmung;
E Innenelektrode;	kV Spannungsmesser;
I Isolator;	A Strommesser

Direct detection of pulses in the gas detector requires internal amplification

Typical gas: Ar/CO₂: 100 e- / cm flight distance

Comparison: solid-state detector ~10000 e-/ 100 μm

2. Ionization Detection

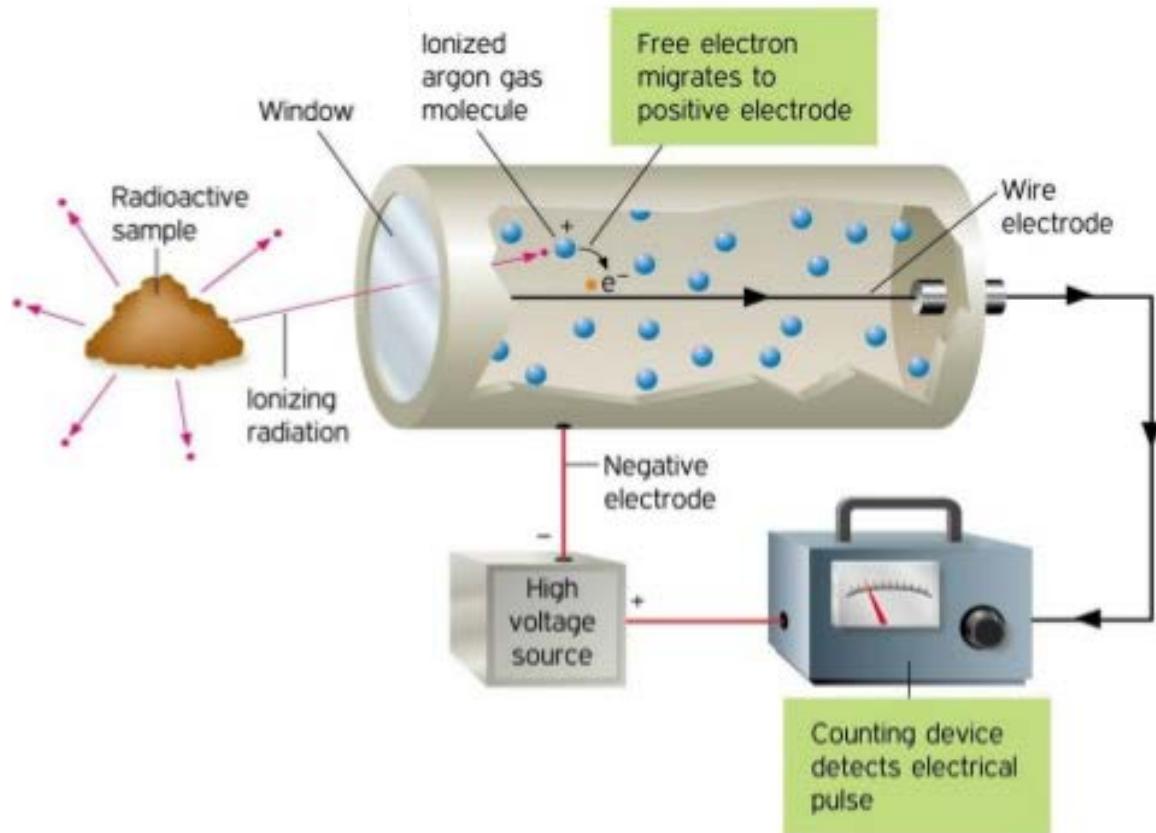

Example: Geiger-Müller counter tube

electric field around wire

$$E(r) = V_0 \frac{1}{r \ln\left(\frac{r_2}{r_1}\right)}$$

r_1 = radius of counting wire

r_2 = radius of tube

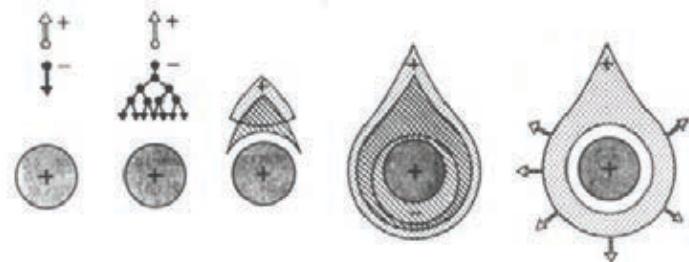

2. Ionization Detection - Gas Amplification

Gas amplification :

Electric fields $\sim \text{kV/cm}$:

- electrons gain sufficient energy between collisions with gas molecules to further ionization
- avalanche charge

Probability of ionization per unit length \sim „Townsend Coefficient“

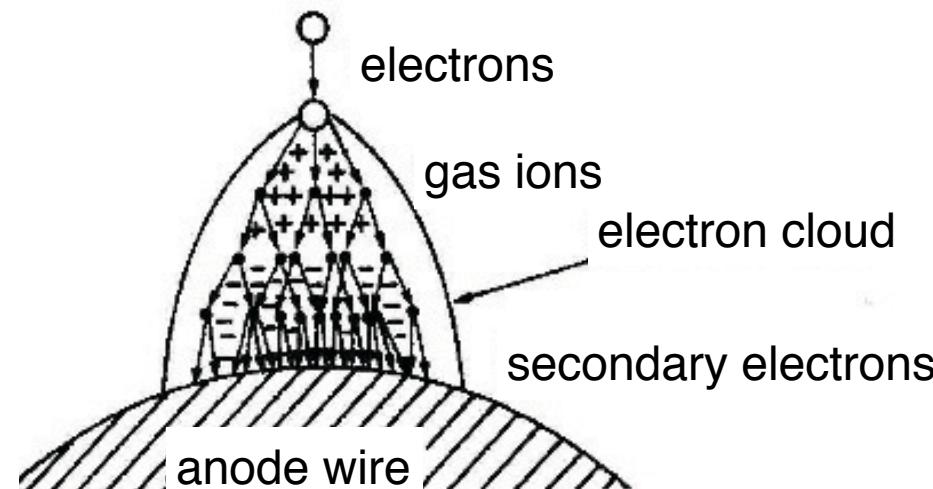

Paschen law

$$\alpha \propto \frac{1}{\lambda} \quad \text{inverse free path length}$$

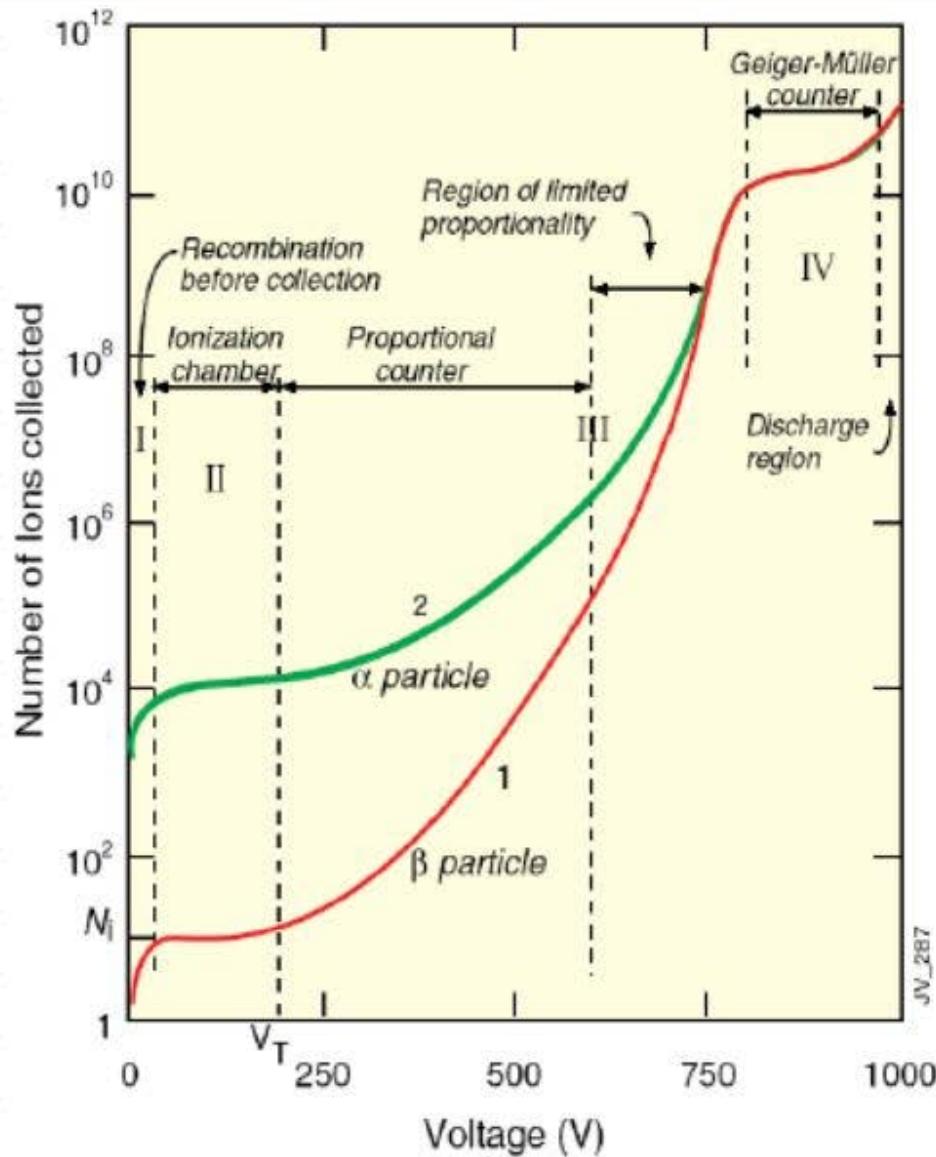

amplification of a detector (“gain”):

$$dN = N \cdot \alpha \cdot dx \rightarrow N = N_0 e^{\alpha \cdot x}$$

$$G = \frac{N}{N_0} e^{\alpha \cdot x}$$

2. Ionization Detection

Typical values for amplification:

- Proportional counter tube $\sim 10^4 - 10^6$
- GEM $\sim 10^3 - 10^5$

In the proportional region, the avalanche charge is proportional to the deposited energy

The maximum avalanche charge is always produced in the Geiger-Müller region

Recapitulation

- What is the electronic energy loss??
 - collisions with atomic electrons with subsequent energy transfer: sum of all processes along a path length dx
- What is the momentum dependence of the energy loss ?
 - drops towards higher γ towards a minimum (3γ), rises and saturates
- What is critical energy and for which particles is it important ?
 - Energy for which electronic and Bremsstrahlung energy-loss are equal (only important for electrons)
- What is multiple scattering and which effect has it ?
 - Sum of many small direction changing collisions with atomic shell electrons. Directional spreading of a particle beam
- What is an ionisation chamber ?
 - Gas volume in which ions are connected in an electric field
- What is an avalanche amplification and where is it used ?
 - Series of processes for the self multiplication of ion pairs in strong electric fields: Geiger-counter

2.1 Ionisation detection

Examples for ionisation detectors:

position sensitive detectors:

beam profiles, imaging (medical applications), particle track determination

MWPC: Multiwire proportional chamber

^3He neutronen detectors

GEM detectors

Drift chambers

TPC: Time projection chambers

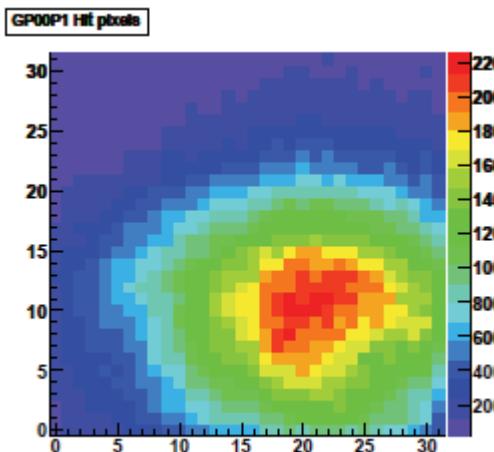

Semiconductor detectors

2.1 Examples: ionisation detection

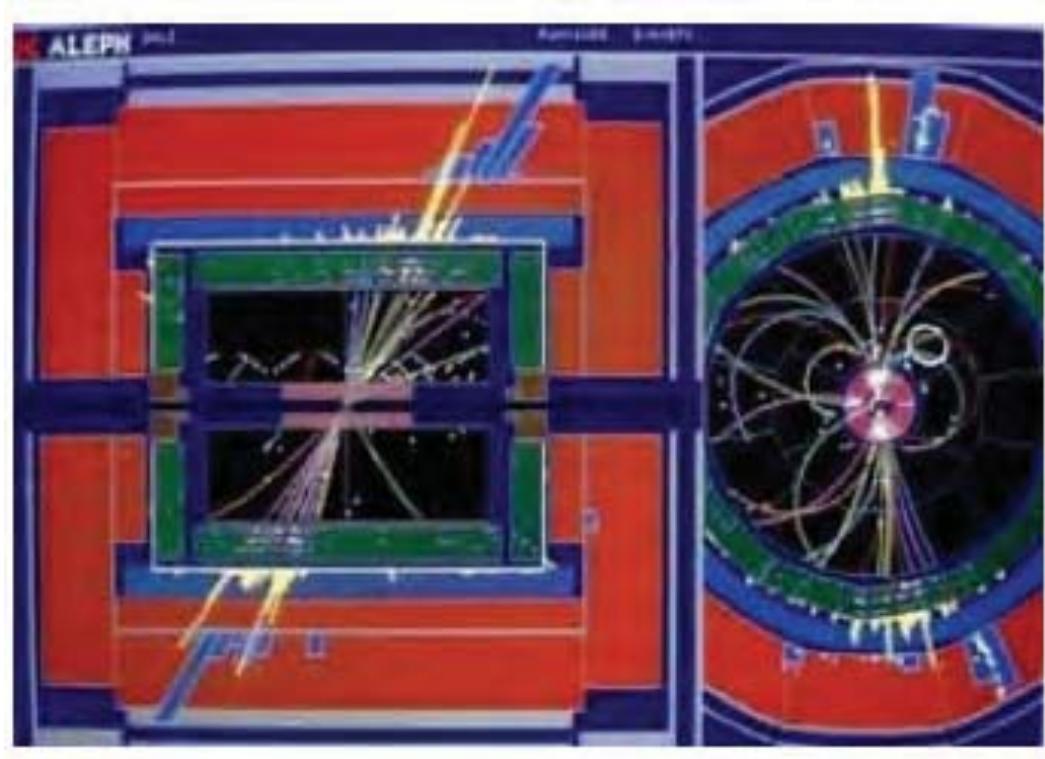

Exzellenzcluster Universe

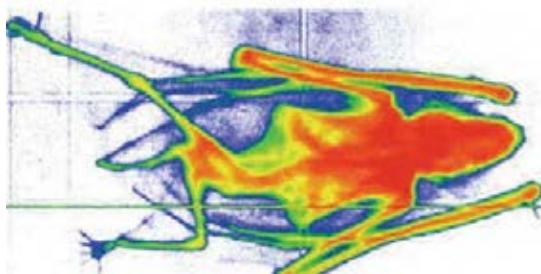

Measurements of beam profiles

Determination of particle tracks and momenta

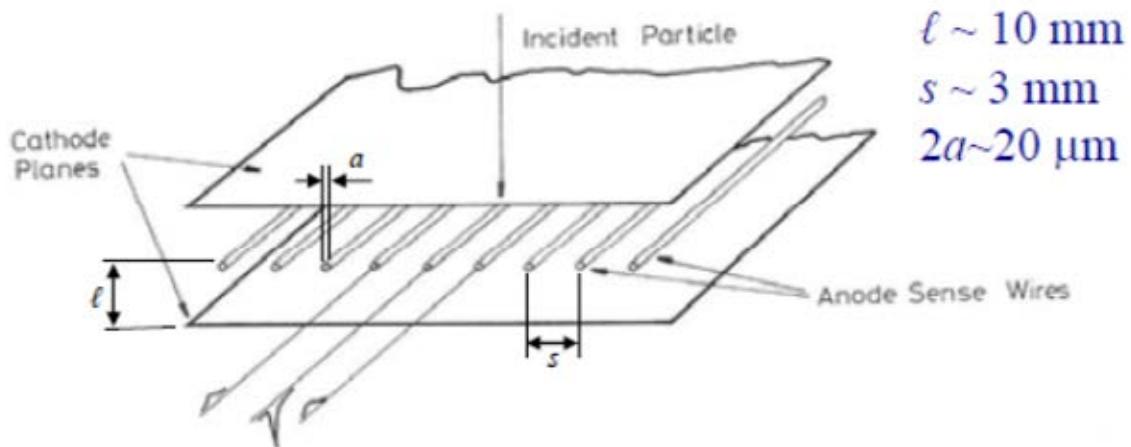

Tomographie (bat)

CERN Courier 2001 Archama Sharma-

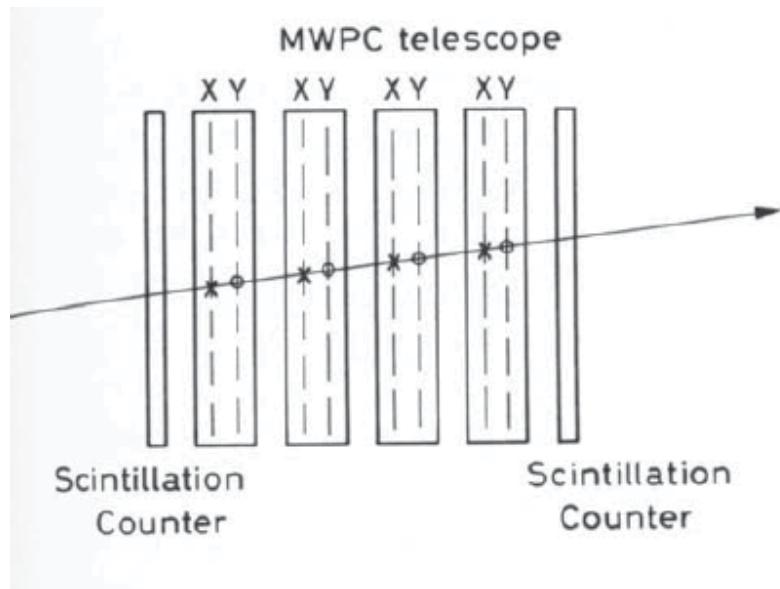

2.1 MWPC

Multi Wire Proportional Chamber

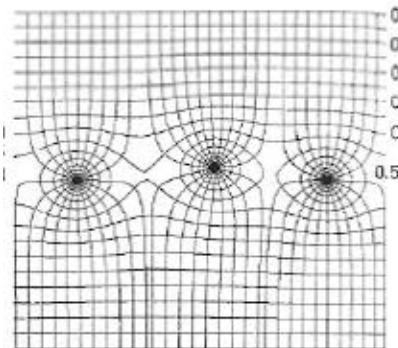

Dimensions:

distances: $l \sim 1 \text{ cm}$, $s \sim 3 \text{ mm}$, $a \sim 10 \mu\text{m}$

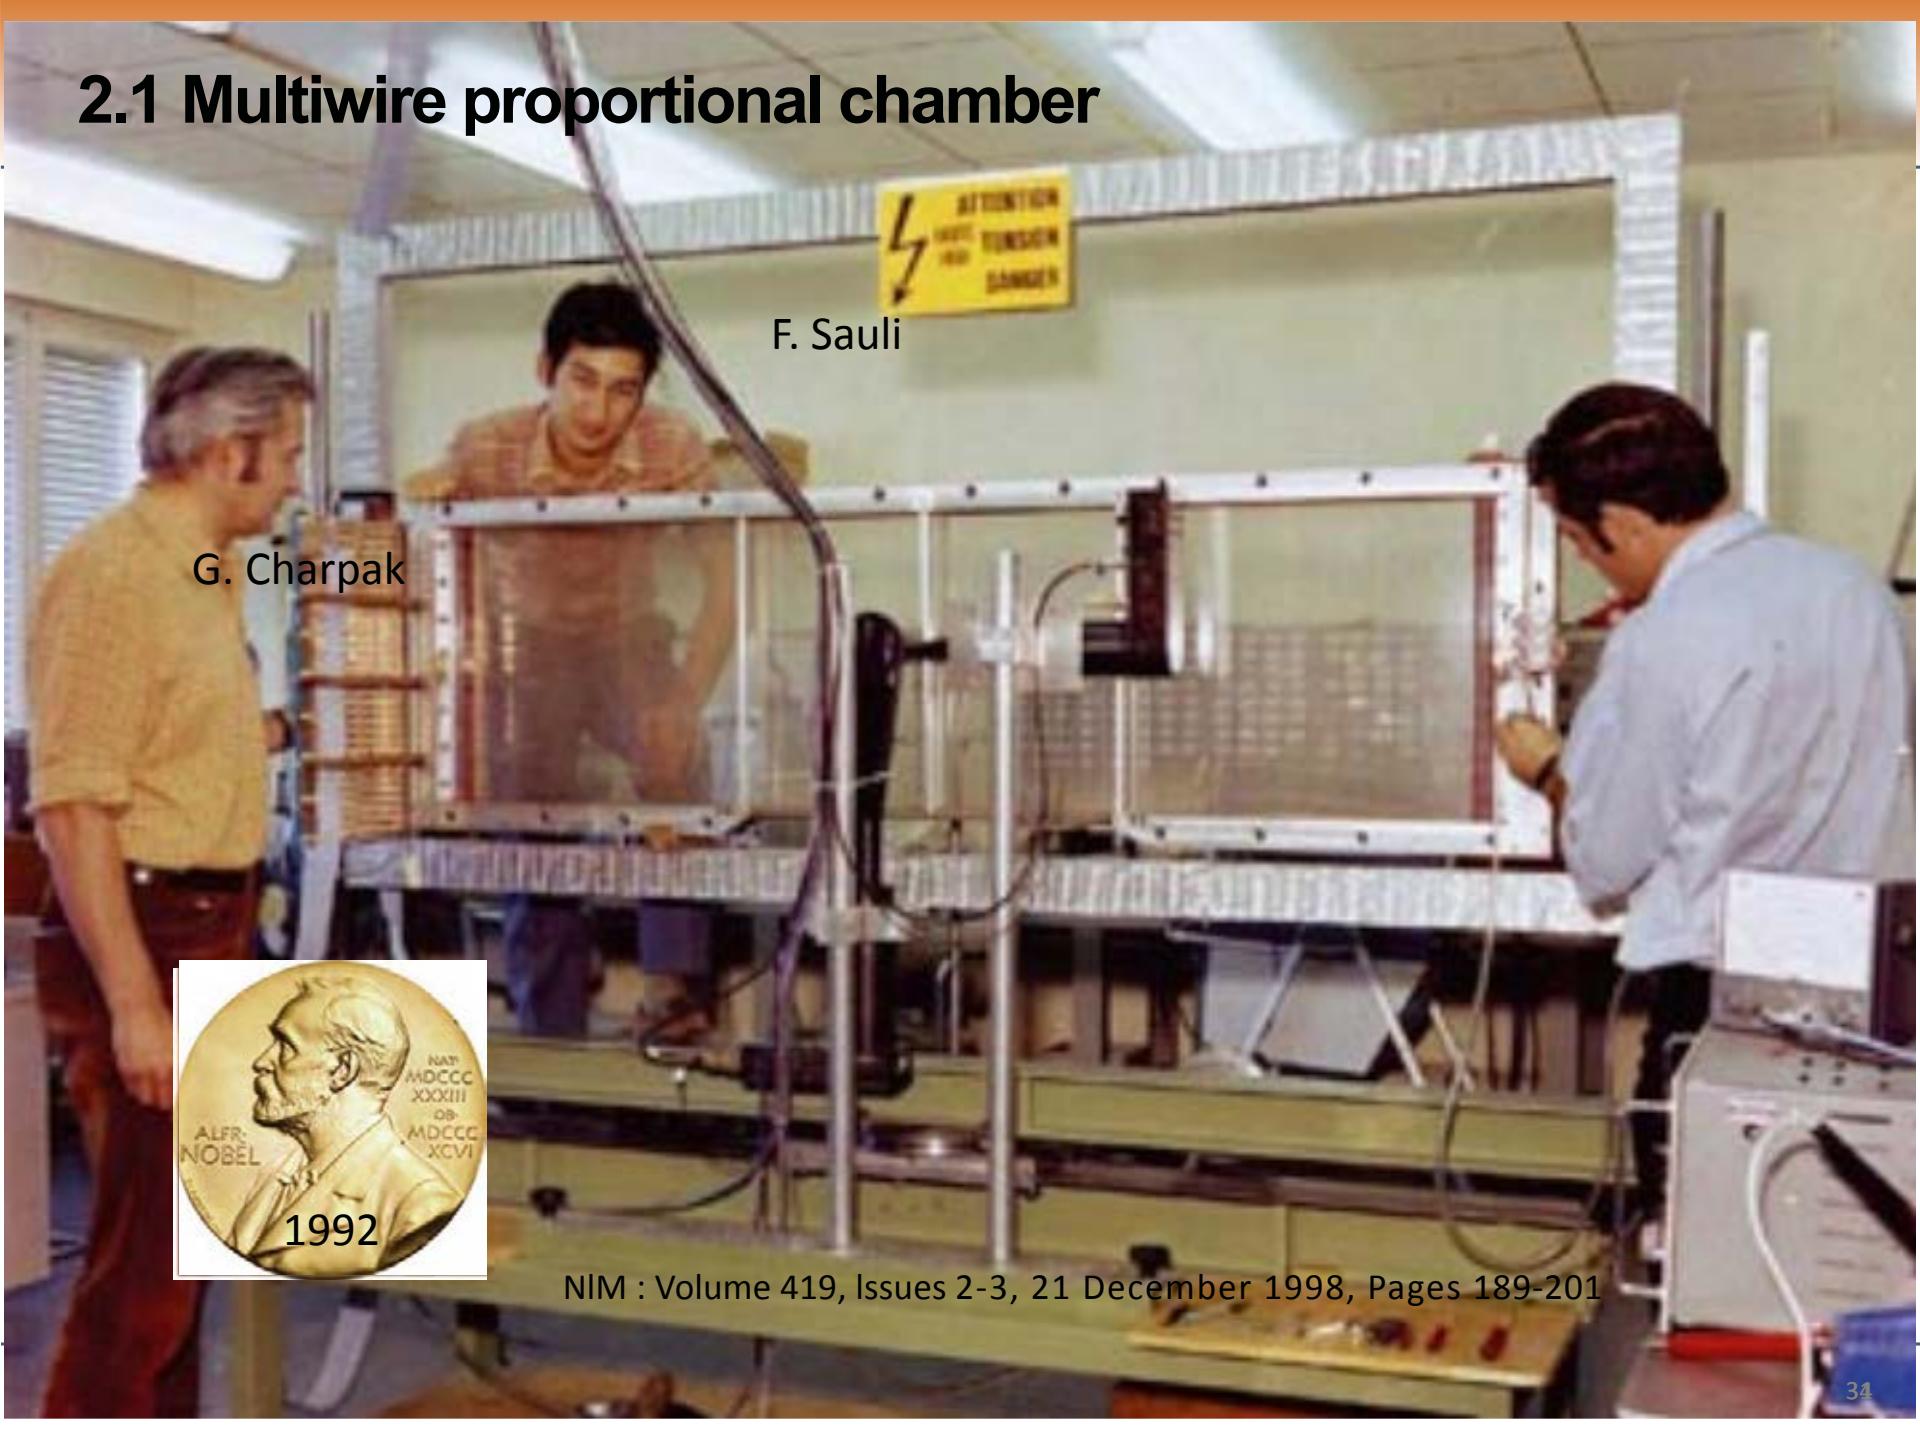

electric field distribution:

pictures:

NIM : Volume 419, Issues 2-3, 21 December 1998, Pages 189-201

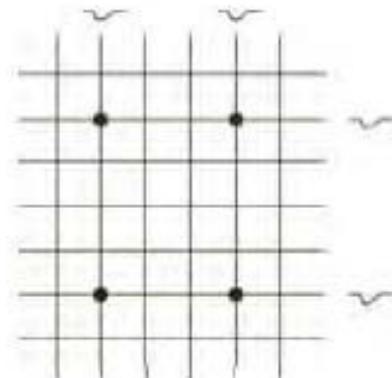

2.1 Ionisation detection

Position detection :

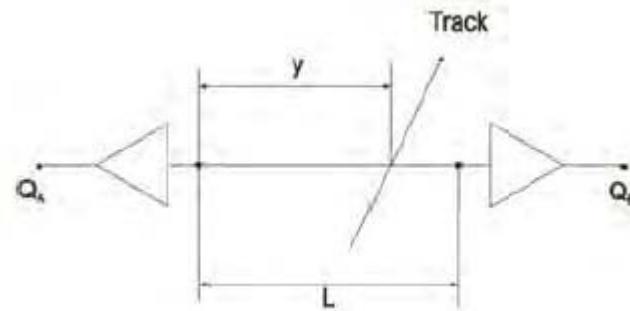

resolution $\sim 50 - 100 \mu\text{m}$

Problem:
ambiguities in x/y
association

sharing of charges:

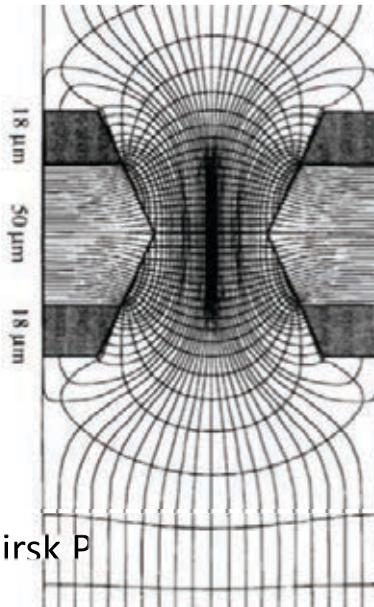

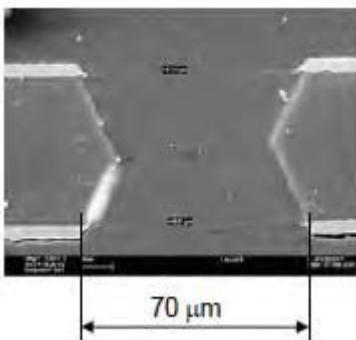

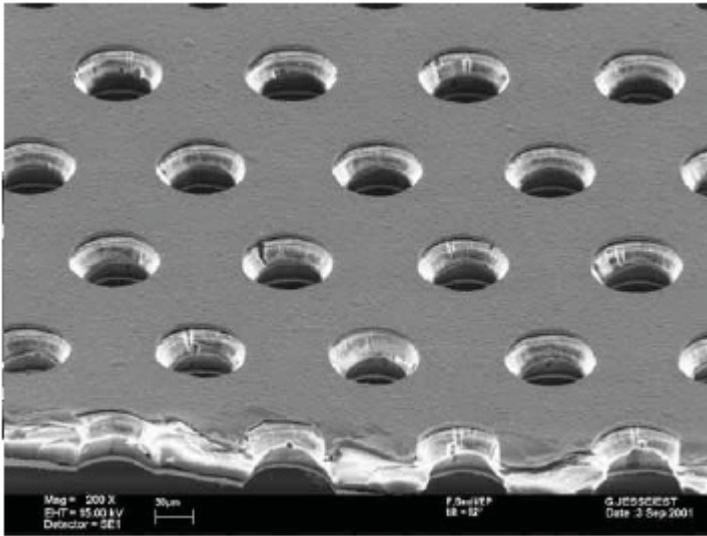

distance from time measurement

typical resolution $\sim \text{cm}$

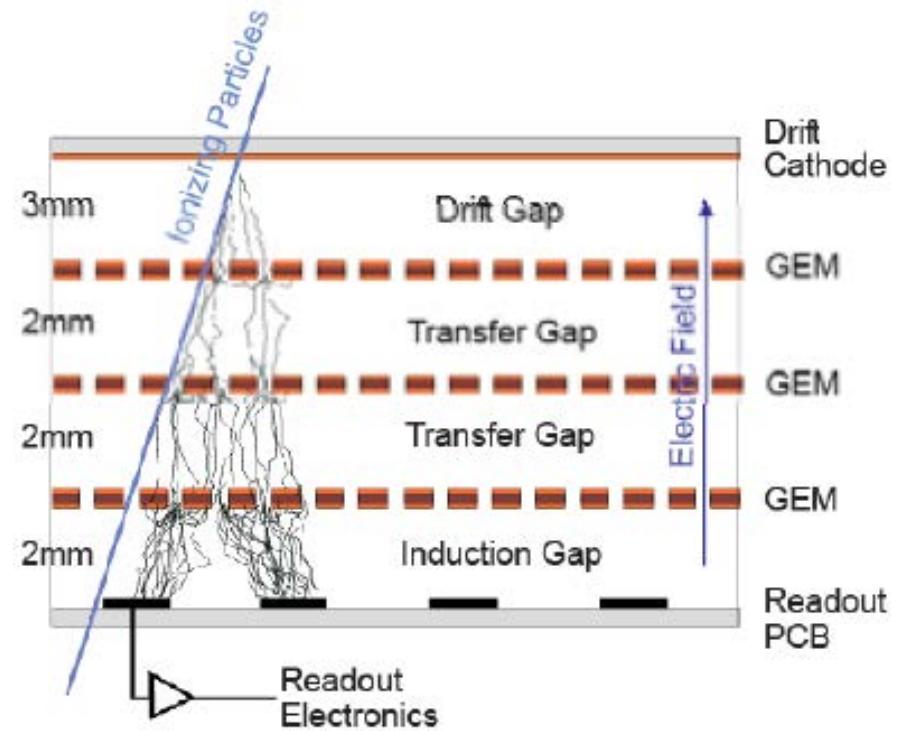

Bilder aus Leo

2.2 GEM Detectors

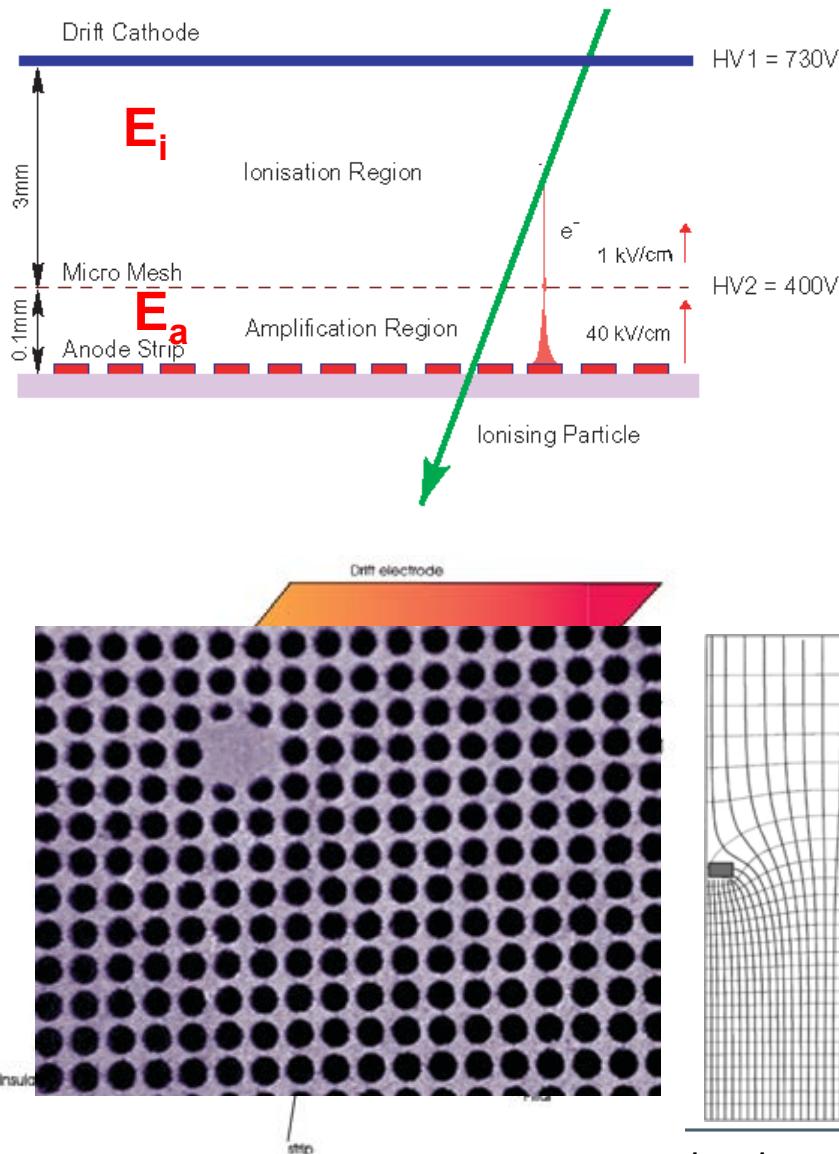

GEM: Gas Electron Multiplier

- better resolution than MWPC (10x)
- amplification stages
- cascading of several foils possible

2.2 Micromegas

Micromesh Gaseous Structure

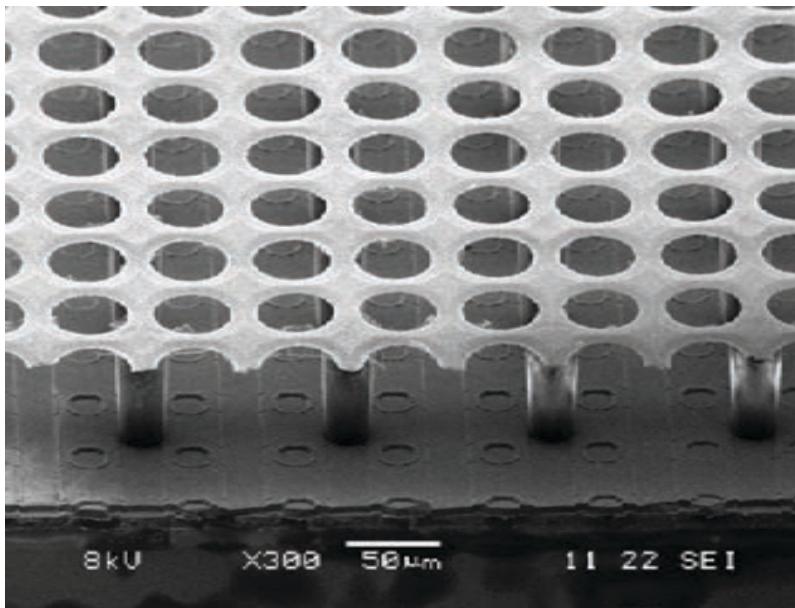

[I. Giomataris et al., NIM A376, 29 (1996)]

- Thin gap parallel plate structure
- Fine metal grid (Ni, Cu) separates conversion (~ 3 mm) and amplification ($\sim 50-100 \mu\text{m}$)
- Very asymmetric field configuration:
 1 kV/cm vs. 50 kV/cm

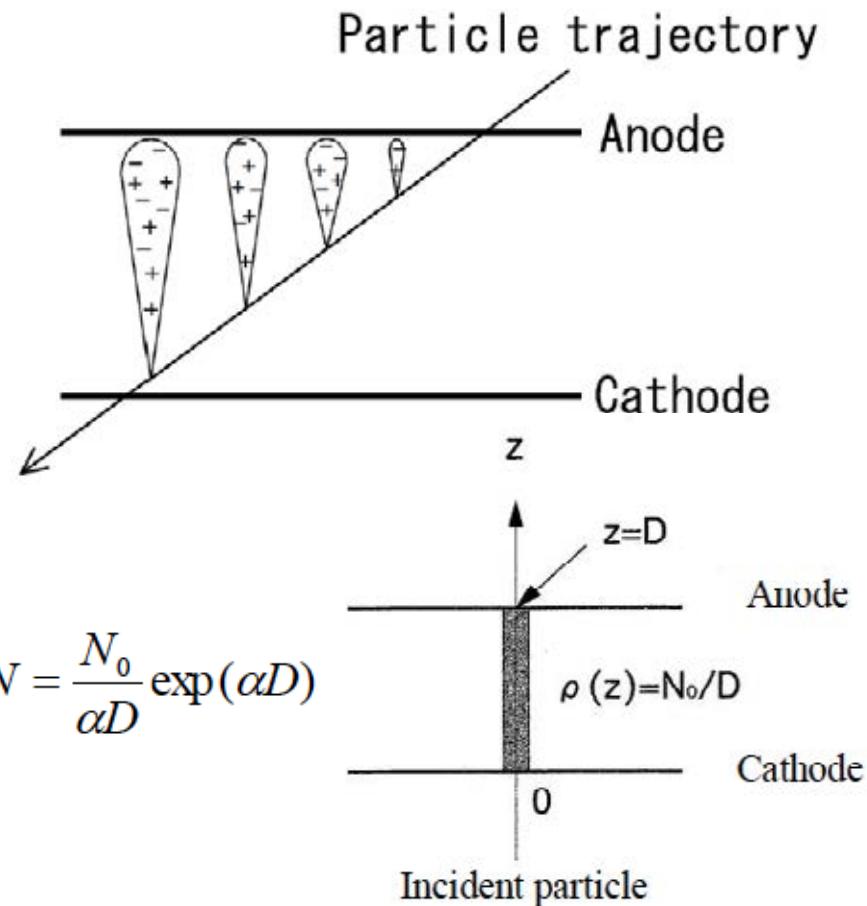

- Fast collection of ions ($\sim 100 \text{ ns}$)
- Saturation of Townsend coefficient (mechanical tolerances)
- good energy resolution

2.2 Micromegas

Mesh with pillars:

Principle of Parallel Plate avalanche detector

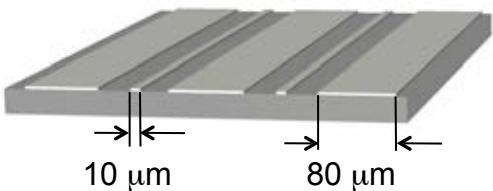

2.2 The MPGD Zoo (Examples)

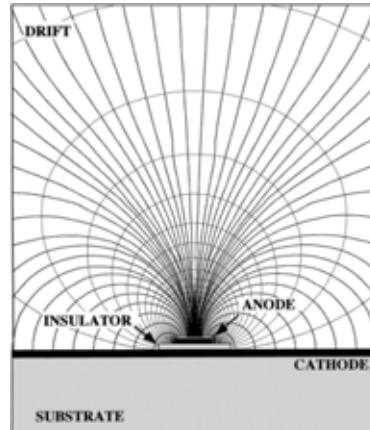

Exzellenzcluster Universe

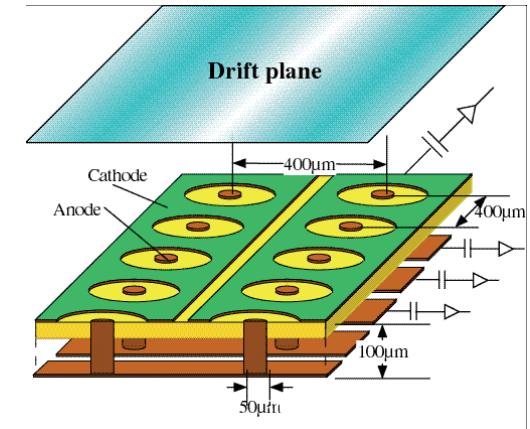

Microstrip Gas Chamber
[A. Oed, NIM A263, 351 (1988)]

Microgap Chamber (MGC)
[F. Angelini et al., NIM A335, 69 (1993)]

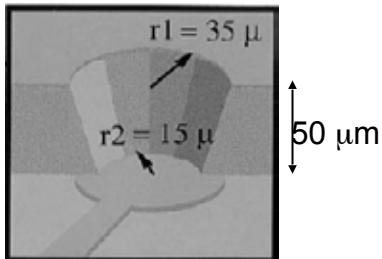

Microdot Chamber
[S.F. Biagi et al., NIM A361, 72 (1995)]

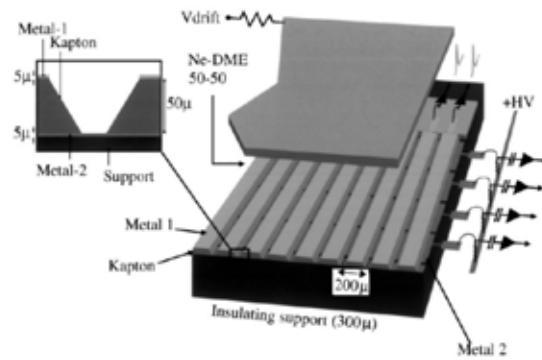

Compteur à Trous (CAT)
[F. Bartol et al., J. Phys. III 6, 337 (1996)]

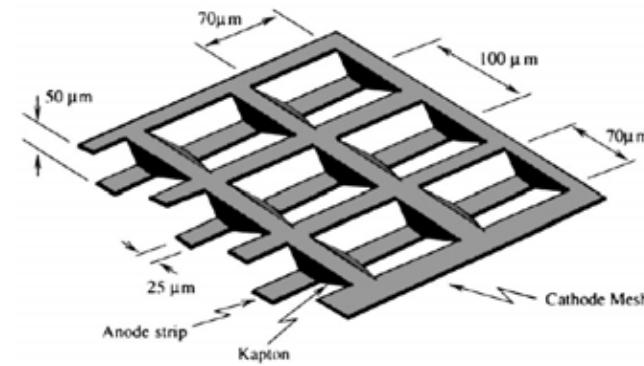

WELL Detector (μ CAT)
[R. Bellazzini et al., NIM A423, 125 (1999)]

Micro Groove Counter
[Bellazzini et al., NIM A424, 444 (1999)]

Micro Wire Detector
[B. Adeva et al., NIM A435, 402 (1999)]

2.3 Drift detectors

- Electrons **drift*** in computing gas with $v=v_D$
- at high E-fields v_D quasi constant
- $v_D(\text{typ})=50 \text{ cm}/\mu\text{s}$

with impact at distance Δx from outing wire

$$\Delta t = \frac{\Delta x}{v_{\text{Drift}}}$$

determine **impact time** t_0 extern (scintillators)

determine t from charge signal at counting wire
from $t-t_0=\Delta T$ obtain **position coordinate**

- good time resolution electronic (1ns)
- spatial resolution: $\sigma_{\text{Ort}} = 100-200 \mu\text{m}$
- wire distance: 2-4cm

small number of electronic channels
keeping excellent spatial resolution

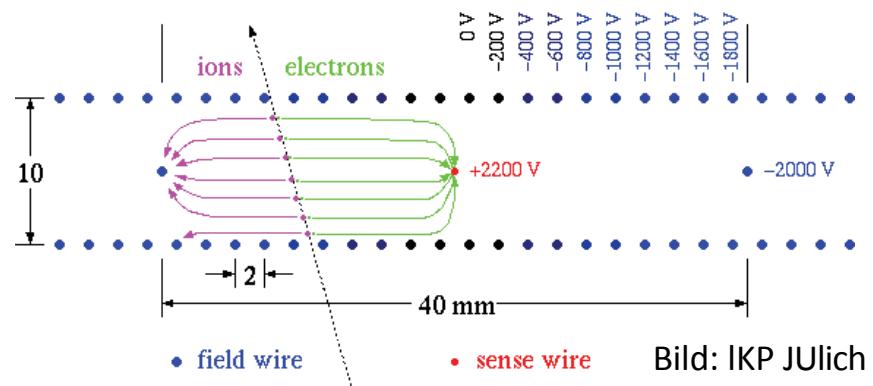

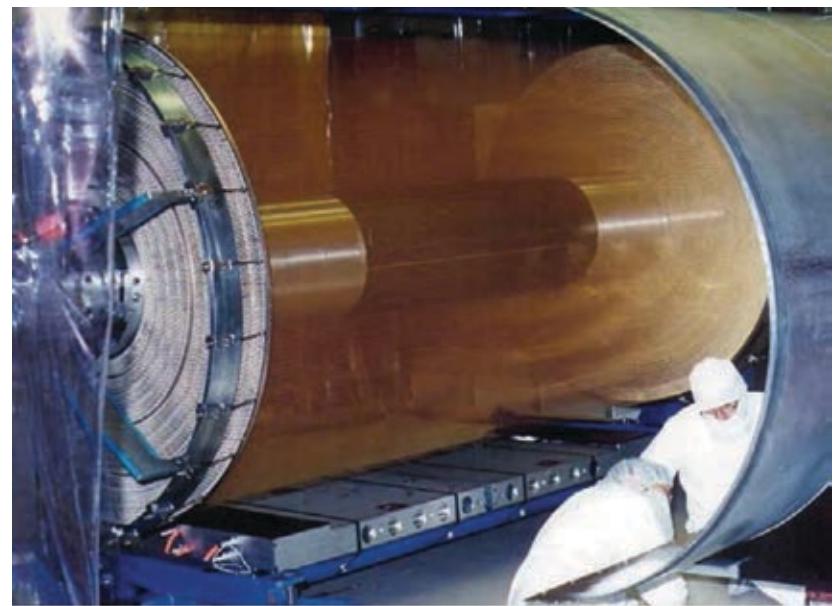

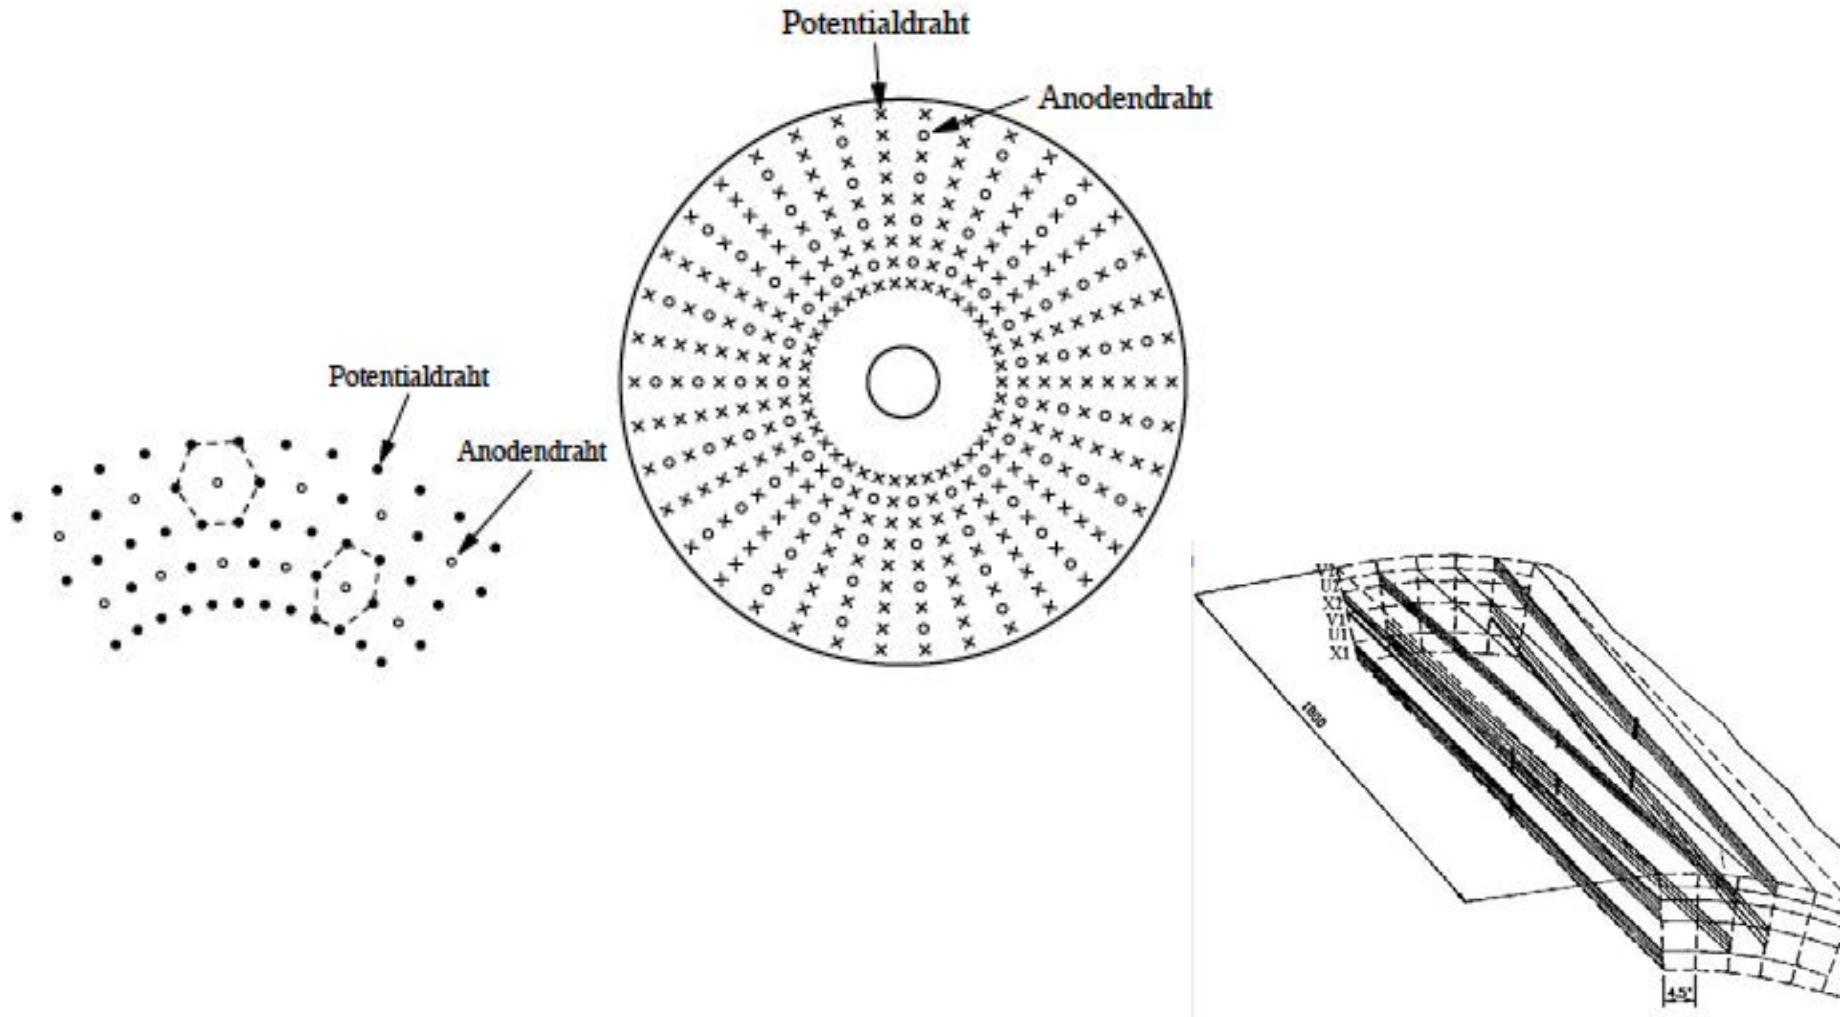

Bild: IKP JUlich

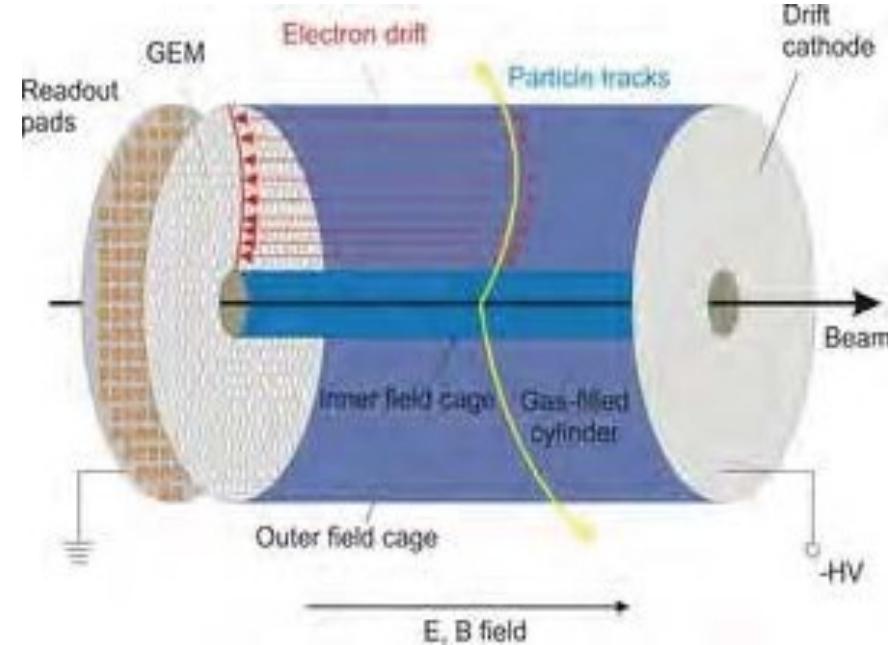

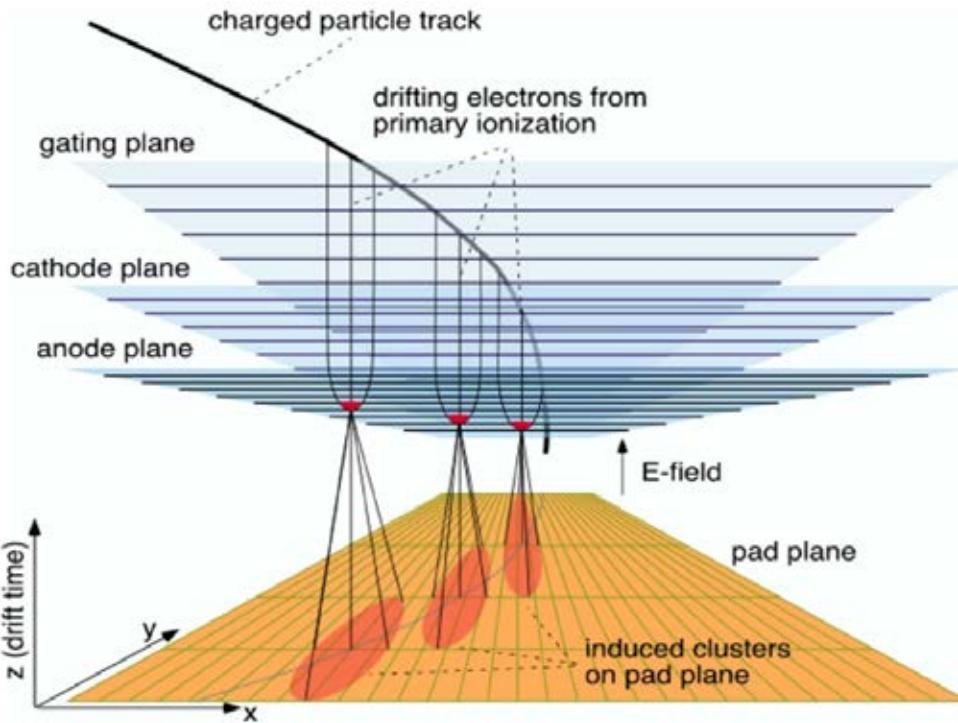

*acceleration in E-field and deceleration through collisions with gas molecules are in balance

2.3 Drift detectors

3D- detection device [D.R. Nygren et al., Phys. Today 31, 46 (1978)]

Combine 2-D planar amplification chamber (e.g. GEM) for x/y coordinates with drift principle for z-coordinate

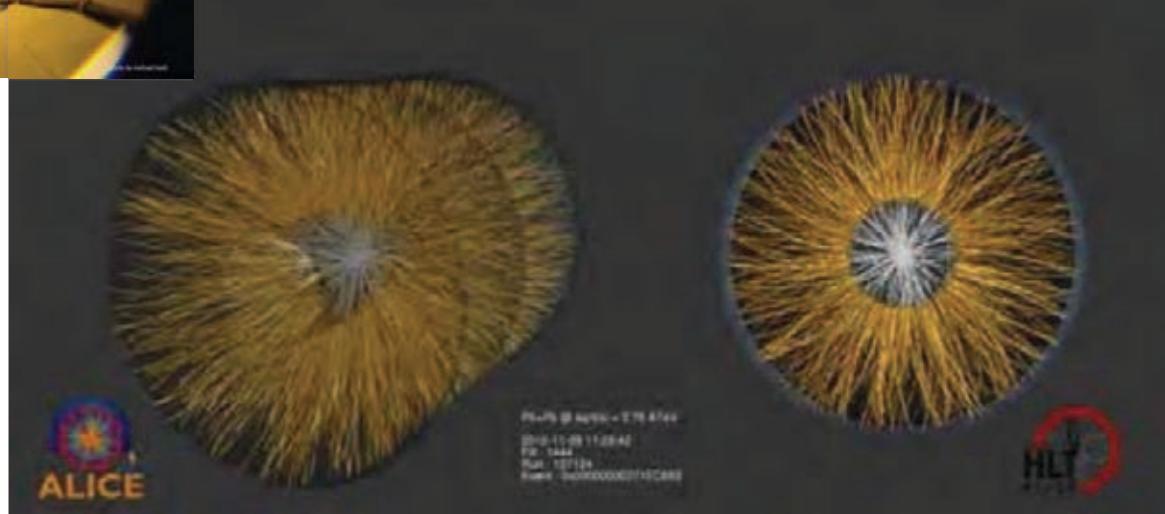

E18 - TUM

2.4 TPC II

ALICE@CERN TPC field cage

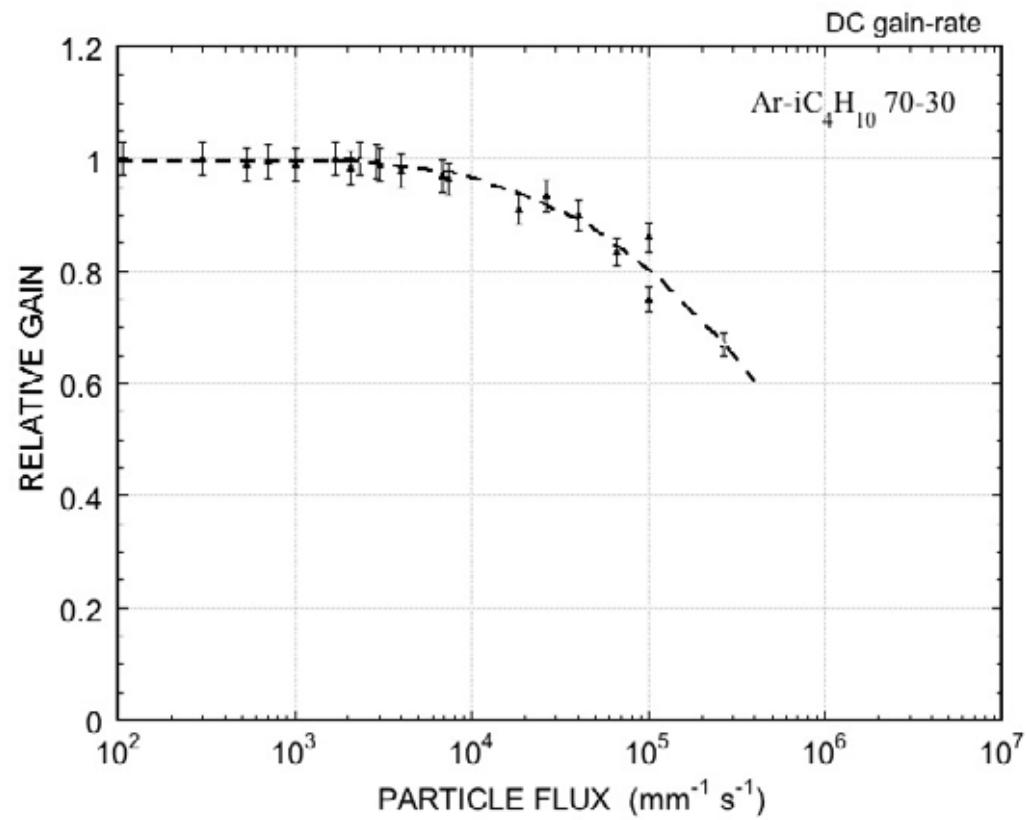

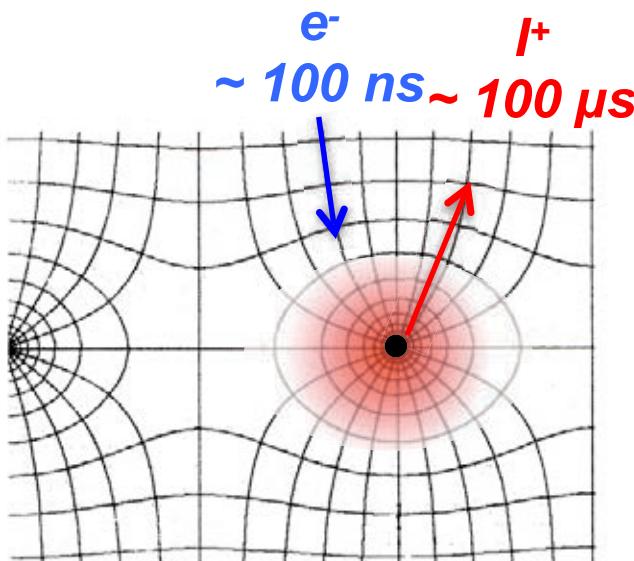

Limitations of Wire-based Detectors

Exzellenzcluster Universe

- Localization accuracy: typ. 100-500 μm
- Volume / 2-track resolution: typ. $10 \times 10 \times 10 \text{ mm}^3$ (signal induction on pads)
- Rate capability: limited by build-up of positive space-charge around anode

[A. Breskin et al., NIM 124, 189 (1974)]

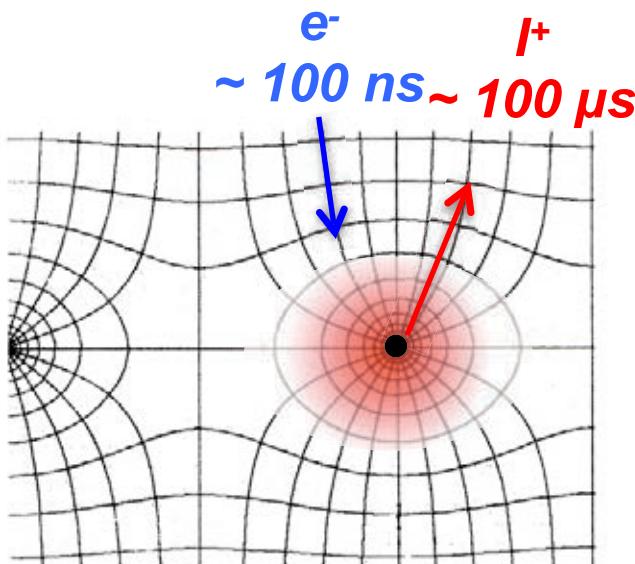

Novosibirsk Physics School - Particle Detectors | Stephan Paul | 17.9.-21.9.2018

Limitations of Wire-based Detectors

Exzellenzcluster Universe

- Localization accuracy: typ. 100-500 μm
- Volume / 2-track resolution: typ. $10 \times 10 \times 10 \text{ mm}^3$ (signal induction on pads)
- Rate capability: limited by build-up of positive space-charge around anode
- Ion backflow: $IB = I_{\text{cathode}} / I_{\text{anode}} \sim 30\%$ for TPC with MWPC

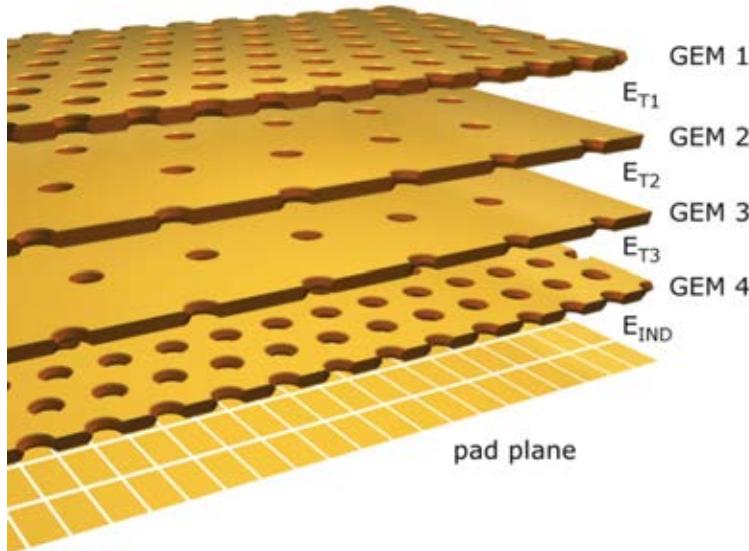

2.4 TPC II

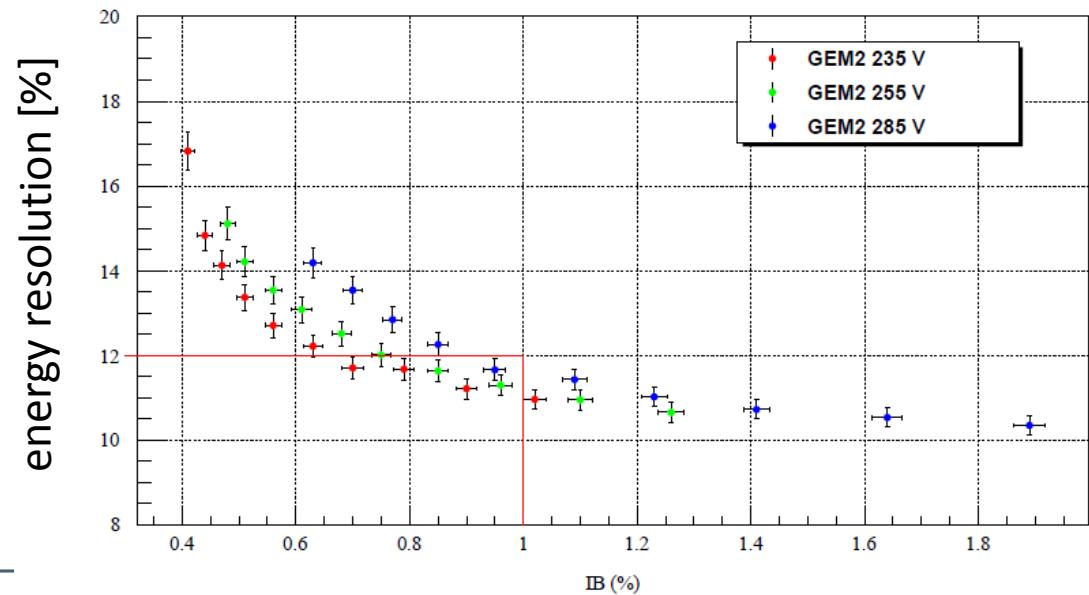

Use GEM detectors to reduce ion feed back problem

This allows continuous readout (film), no gating of amplification region required

2.4 Ion Backflow – ALICE Solution

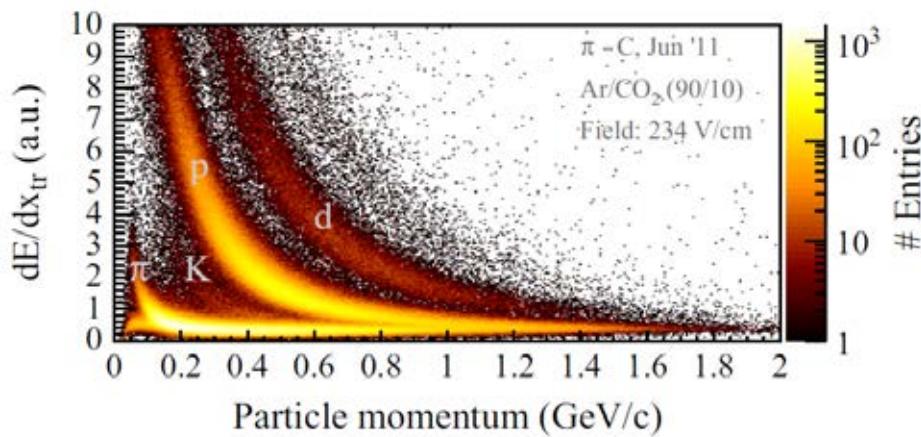

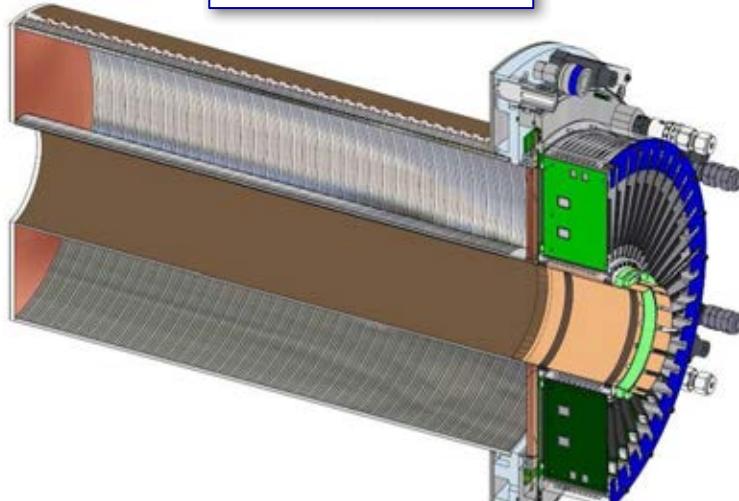

- Triple-GEM setup not sufficient
- New chambers: 4-GEM setup with standard (S) and large pitch (LP)
- Field configuration optimized to provide
 - $IB < 1\%$
 - $\sigma_E/E < 12\%$ (for ^{55}Fe X-rays)
 - Discharge stability

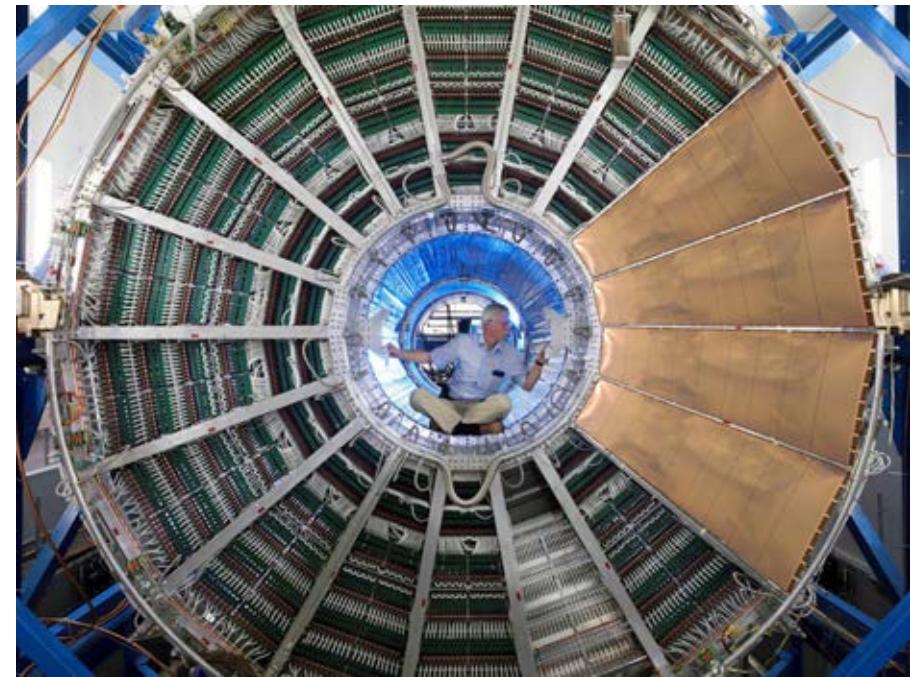

2.4 GEM-TPC
