Why particle identification?

Ring Imaging Cherenkov counters

TOF

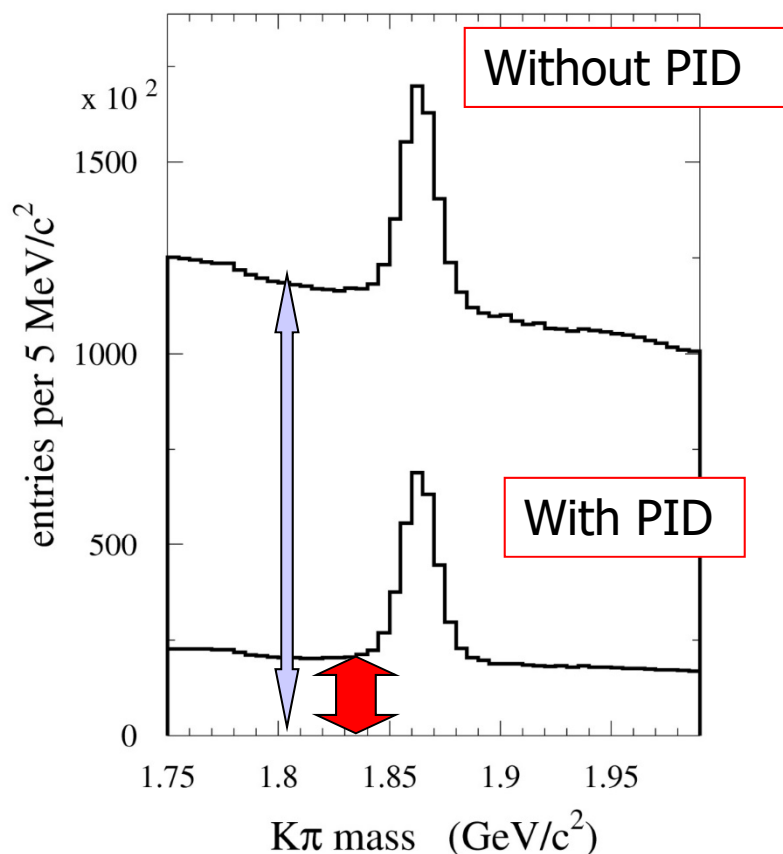

Transition radiation detectors

Summary

Why particle ID?

Example 1: B factories

Particle identification reduces the fraction of wrong $K\pi$ combinations (combinatorial background) by $\sim 5x$

Particle identification at B factories (Belle and BaBar): was essential for the observation of CP violation in the B meson system.

Why particle ID?

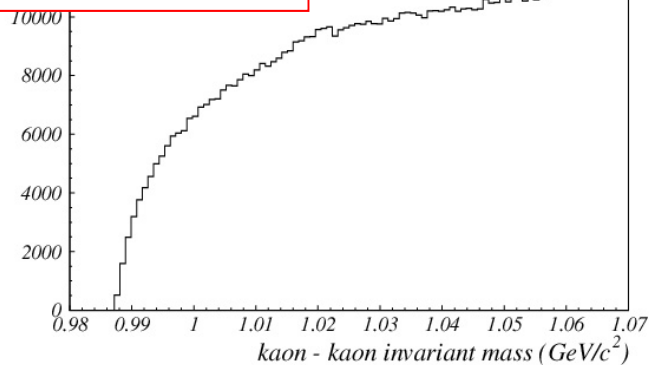

Example 2: LHCb

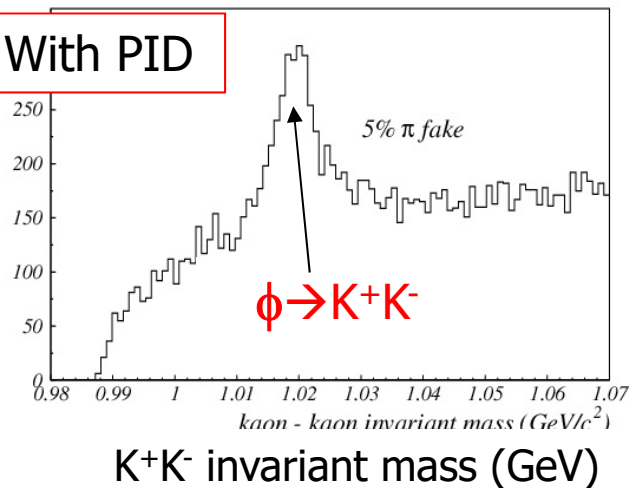

Need to distinguish $B_d \rightarrow \pi\pi$ from other similar topology 2-body decays and to distinguish B from anti-B using K tag.

Why particle ID?

Without PID

With PID

Example 3: HERA-B, the inclusive $\phi \rightarrow K^+K^-$ decay only becomes visible after particle identification is taken into account.

PID is also needed in:

- General purpose LHC experiments: final states with electrons and muons
- Searches for exotic states of matter (quark-gluon plasma)
- Spectroscopy and searches for exotic hadronic states
- Studies of fragmentation functions

Example: Belle

Particle identification systems in Belle

Particle identification methods depend on the requirements (physics channel, kinematics)

Example: B factory, pion/kaon separation

Tagging Kaons

Relatively soft,
ms dominated
for tracking

$B \rightarrow \pi\pi$

Requires
dedicated PID

$B \rightarrow DK$

Requires
dedicated PID

PID coverage of kaon/pion spectra in Belle

Tagging Kaons

$B \rightarrow \pi\pi$

$B \rightarrow DK$

Efficiency and purity in particle identification

Efficiency and purity are tightly coupled!

Two examples:

particle type 1 type 2

efficiency vs fake probability
(for Gaussian distributions)

some discriminating variable x , scaled to the resolution σ_x

Identification of charged particles

Particles (e, μ , π , K, p) in the final state are identified by their **mass** or by the **way they interact**.

Determination of **mass**: from the relation between momentum and velocity, $p = \gamma m v$ (p is known - radius of curvature in the magnetic field)

→ Measure velocity by:

- time of flight
- ionisation losses dE/dx
- Cherenkov photon angle (and/or yield)
- transition radiation

Mainly used for the identification of hadrons.

Identification through **interaction**: electrons and muons

- muon systems
- calorimeters

Identification of charged particles

Particles (e, μ , π , K, p) in the final state are identified by their **mass** or by the **way they interact**.

Determination of **mass**: from the relation between momentum and velocity, $p = \gamma m v$ (p is known - radius of curvature in magnetic field)

→ Measure velocity by:

- time of flight
- ionisation losses dE/dx
- Cherenkov photon angle (and/or yield)
- transition radiation

Mainly used for the identification of hadrons.

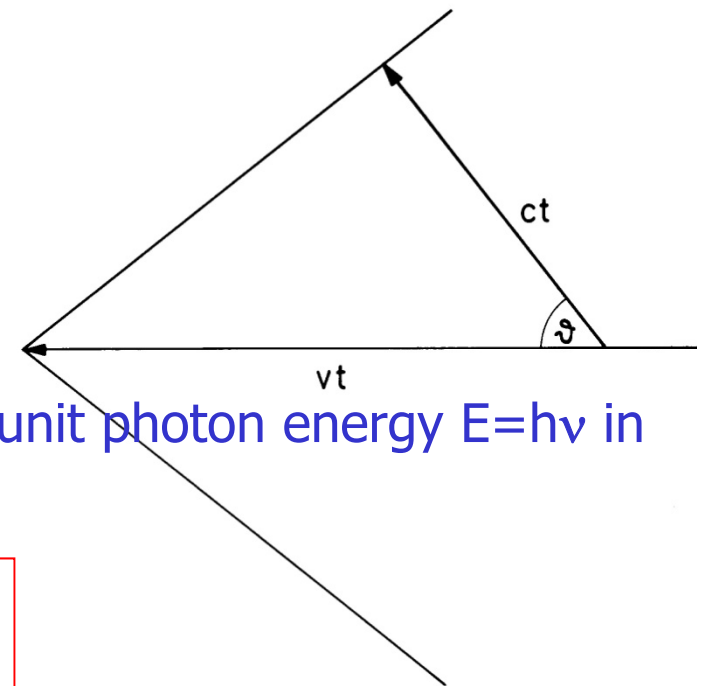

Identification through **interaction**: electrons and muons

- muon systems
- calorimeters

Cherenkov radiation

A charged track with velocity $v = \beta c$ exceeding the speed of light c/n in a medium with refractive index n emits **polarized light** at a characteristic (Cherenkov) angle (for $\beta > 1/n$ - above threshold)

$$\cos\theta = c/nv = 1/\beta n$$

The number of Cherenkov photons emitted over unit photon energy $E = h\nu$ in a radiator of length L :

$$\frac{dN}{dE} = \frac{\alpha}{\hbar c} L \sin^2 \theta = 370(\text{cm})^{-1} (\text{eV})^{-1} L \sin^2 \theta$$

→ Few detected photons

Measuring the Cherenkov angle

Particles above threshold: measure θ

Idea: transform the direction into a coordinate \rightarrow ring on the detection plane \rightarrow Ring Imaging Cherenkov (RICH) counter

Proximity focusing RICH

RICH with a focusing mirror

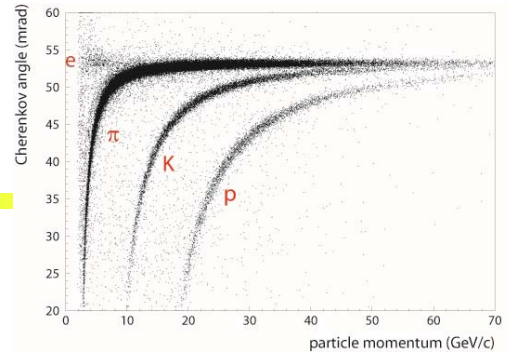

Measuring Cherenkov angle

Radiator:
 C_4F_{10} gas

↑ π ↑ K ↑ p

Resolution of a RICH counter

Determined by:

- Photon impact point resolution (\sim photon detector granularity)
- Emission point uncertainty (not in a focusing RICH)
- Dispersion: $1/\beta = n(\lambda) \cos\theta$
- Errors of the optical system
- Uncertainty in track parameters

Resolution per track:

$$\sigma_{track} = \frac{\sigma_0}{\sqrt{N_{pe}}}$$

σ_0 ← single photon resolution
 N_{pe} ← # of detected photons

(in the case of low background)

Photon detection in RICH counters

RICH counter: measure photon impact point on the photon detector surface

→ detection of **single** photons with

- sufficient **spatial resolution**
- **high efficiency** and **good signal-to-noise** ratio (few photons!)
- over a **large area** (square meters)

Special requirements:

- **Operation in magnetic field**
- High rate capability
- **Very high spatial resolution**
- **Excellent timing** (time-of-arrival information)

Photon detector is the most crucial element of a RICH counter

Cherenkov counters in LHC-like environments

Operation at **high rates** ($\sim 1 \text{ MHz/cm}^2$) over **extended running periods** (years)
→ Need **vacuum based photon detectors** (e.g. PMTs)

Good spacial resolution (pads with $\sim 5 \text{ mm}$ size) → Solution: **multianode PMTs** (MaPMTs) and **hybrid photodetectors** (HPDs)

Multianode PMTs

Multianode PMTs (MaPMTs) with metal foil dynodes and 2x2, 4x4 or 8x8 anodes Hamamatsu R5900 (and follow up types 7600, 8500)

→ Excellent single photon pulse height spectrum

→ Low noise (few Hz/ch)

→ Low cross-talk (<1%)

→ NIM A394 (1997) 27

HERA-B RICH

Photon detector requirements:

- High QE over $\sim 3\text{m}^2$
- Rates $\sim 1\text{MHz}$
- Long term stability

HERA-B RICH photon detector

Light collection system (imaging!) to:

- Eliminate dead areas
- Adapt the pad size

-A similar set-up also employed in the COMPASS RICH (quartz lenses)

HERA-B RICH

← Little noise, ~ 30 photons per ring

Typical event →

Worked very well!

Kaon efficiency and pion fake probability

Kinematic range of a RICH counter

Example: kinematic range for kaon/pion separation

Kinematic range for separation of two particle types:

- Lower limit p_{\min} : sufficiently above lighter particle threshold
- Upper limit p_{\max} : given by Cherenkov angle resolution – overlap of the two bands

Rule of thumb: $p_{\max} / p_{\min} < 10$

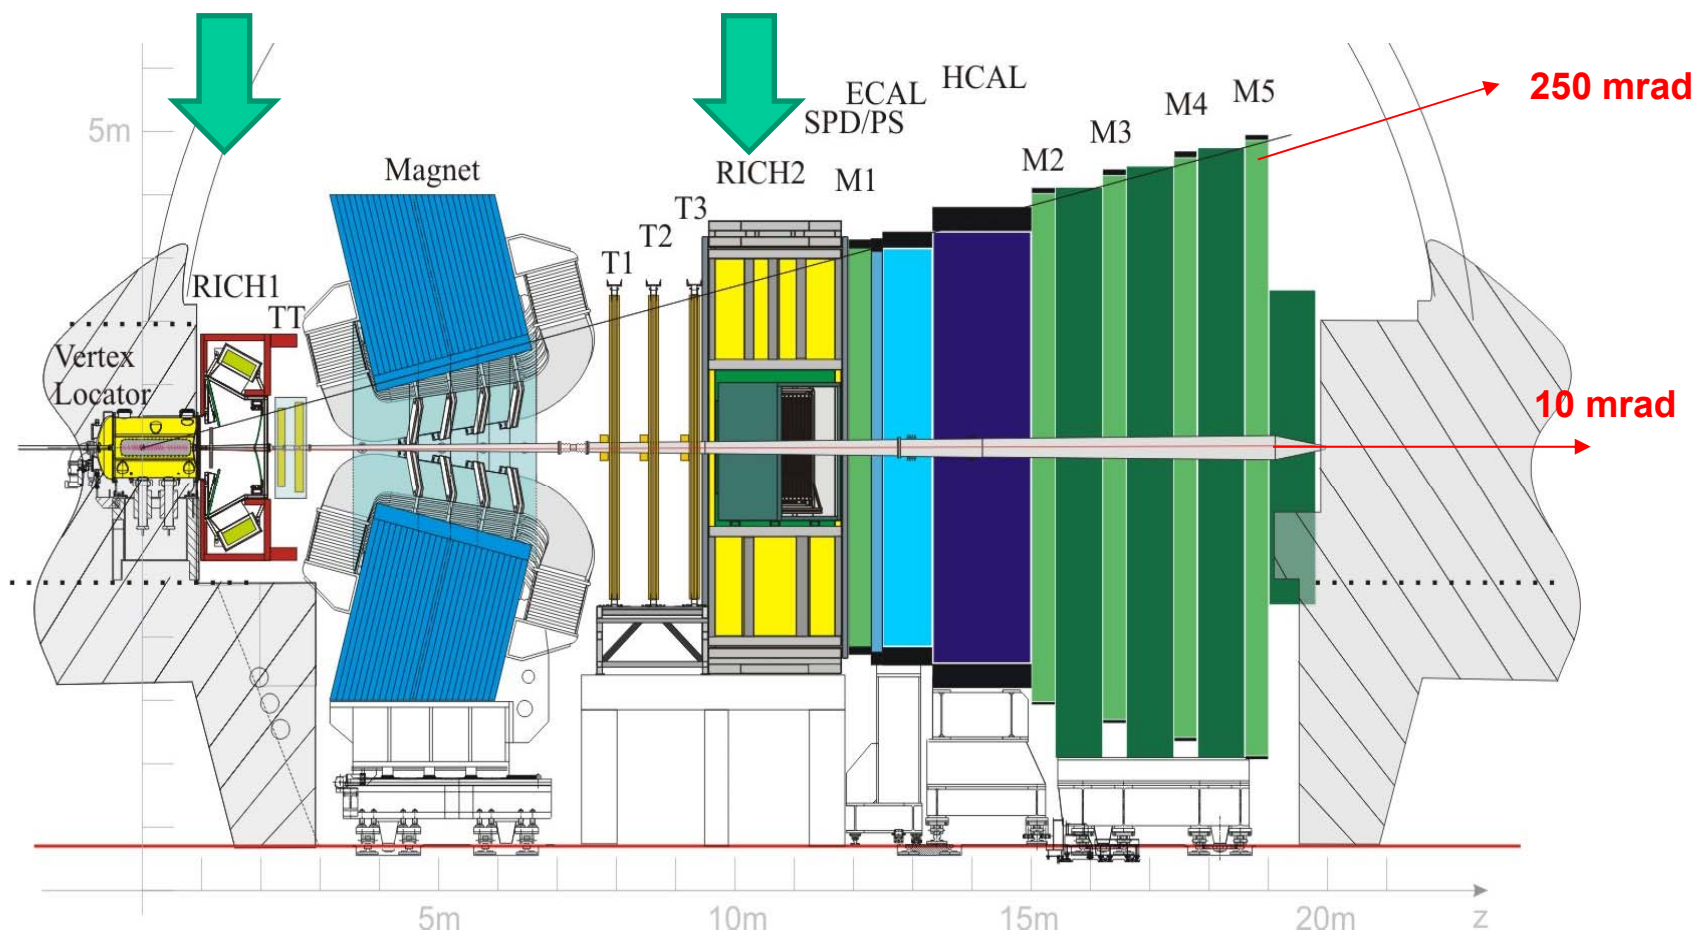

RICHes with several radiators

Extending the kinematic range → need more than one radiator

- DELPHI at LEP, SLD at SLC (liquid + gas)
- HERMES at HERA (aerogel+gas)

The LHCb RICH counters

Vertex reconstruction:
VELO

Trigger:
Muon Chambers
Calorimeters
Tracker

PID:
RICHes
Calorimeters
Muon Chambers

Kinematics:
Magnet
Tracker
Calorimeters

LHCb RICHes

Need:

- Particle identification for momentum range $\sim 2\text{-}100\text{ GeV}/c$
- Granularity $2.5 \times 2.5\text{ mm}^2$
- Large area (2.8 m^2) with high active area fraction
- Fast compared to the 25ns bunch crossing time
- Have to operate in a small B field

→ 3 radiators

- Aerogel
- C_4F_{10} gas
- CF_4 gas

LHCb RICHes

LHCb RICHes

Photon detector: hybrid PMT (R+D with DEP) with 5x demagnification (electrostatic focusing).

Hybrid PMT: accelerate photoelectrons in electric field ($\sim 20\text{kV}$), detect them in a pixelated silicon detector.

NIM A553 (2005) 333

Performance of LHCb RICHes

Single event

LHCb RICHes: performance

“Search for CP violation in $\Lambda_b^0 \rightarrow pK^-$ and $\Lambda_b^0 \rightarrow p\pi^-$ decays”
 [LHCb-PAPER-2018-025]

LHCb Upgrade (well under way)

- ❑ New photon detectors: MaPMTs Hamamatsu R13743 (H12700) and R13742 (R11265)
- ❑ New electronics working at 40 MHz readout rate
- ❑ New optics layout for RICH 1

INSTR20

→ Talk by Antonios Papanestis

Future LHCb Upgrade

- ❑ Provide PID at p-p luminosity of $10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ in the forward region
- ❑ Incremental improvements in:
 - Improve Cherenkov angle resolution
 - More photons in the green \rightarrow lower chromatic error
 - Reduced event complexity with timing
 - Enhanced number of photons

Radiator	C_4F_{10}			CF_4	
	RICH 1 Current (HPD)	RICH 1 UPG1	RICH 1 UPG2	RICH 2 UPG1	RICH 2 UPG2
Average Photoelectron Yield	30	40	60–30	22	30
Single Photon Errors (mrad)					
Chromatic	0.84	0.58	0.24–0.12	0.31	0.1
Pixel	0.9	0.44	0.15	0.20	0.07
Emission Point	0.8	0.37	0.1	0.27	0.05
Overall	1.47	0.82	0.3–0.2	0.46	0.13

NA62 RICH

- ❑ Momentum range 15-35 GeV/c
- ❑ 17m long, 200m³ cylindrical vacuum proof tank with Neon radiator
- ❑ Photon detectors: 2000 PMTs (16mm, 8mm active, with Winstone cone light guides)
- ❑ Mirror alignment $\sim 30 \mu\text{rad}$
- ❑ Single photon resolution: $\sim 140 \mu\text{rad}$
- ❑ Operational since 2014

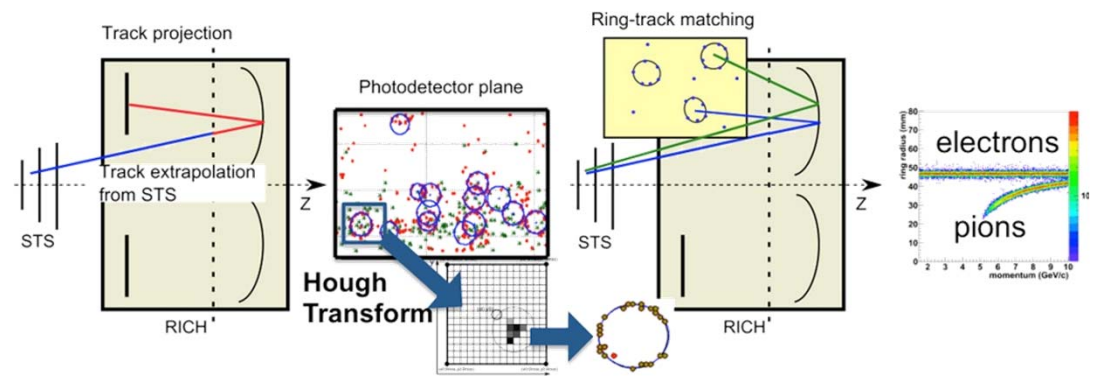

CBM

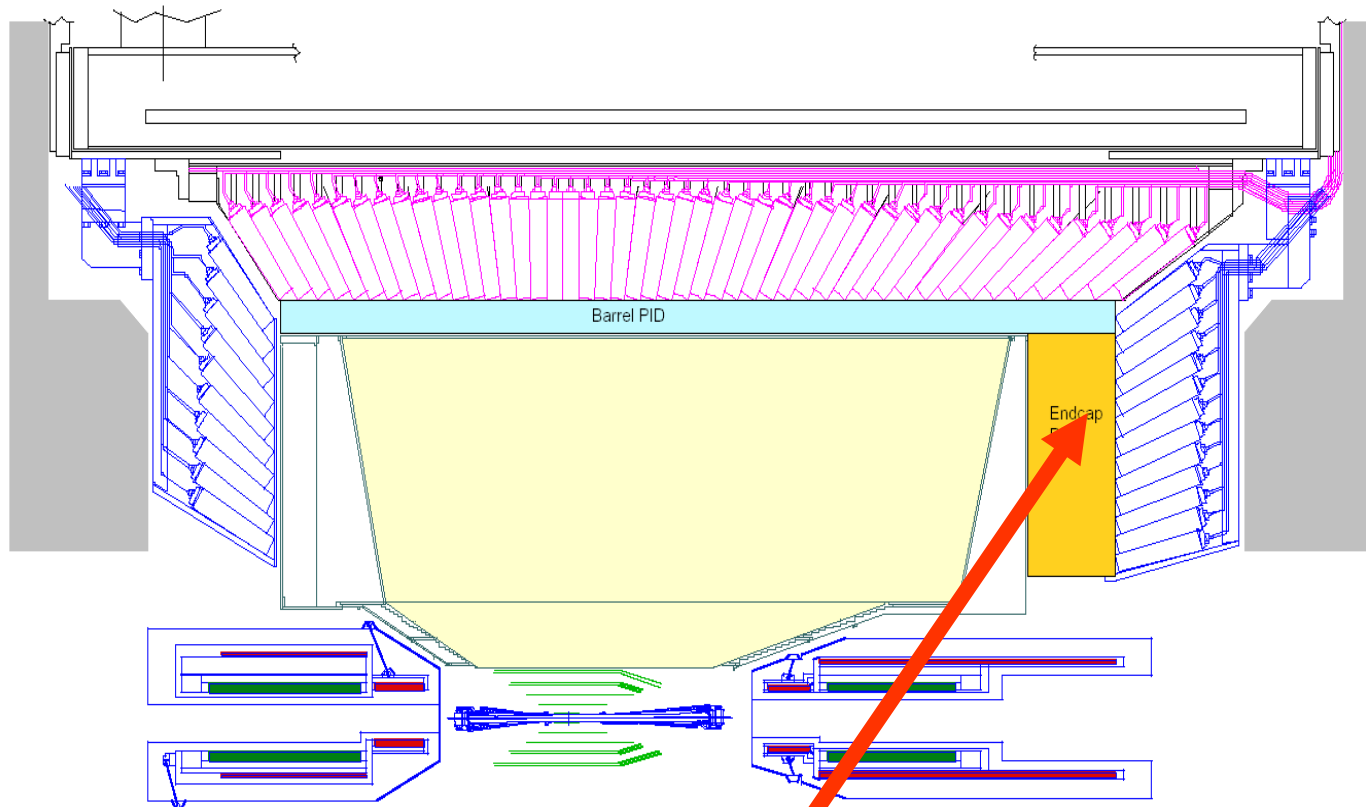

- ❑ RICH with CO₂ radiator
- ❑ MaPMTs: Hamamatsu H12700
- ❑ Cylindrical photon detection surface
- ❑ Extensive testing of MaPMTs for radiation damage
- ❑ Up to 1000 tracks per event
- ❑ Momentum up to 8 GeV/c
- ❑ Pion suppression factor ~ 5000 (with TRD)

Belle II PID system

Two novel particle ID devices, both RICHes:

Barrel: Time-of-propagation counter (TOP) counter

Endcap: proximity focusing RICH

Endcap: Proximity focusing RICH

K/ π separation at 4 GeV/c:
 $\theta_c(\pi) \sim 308$ mrad ($n = 1.05$)
 $\theta_c(\pi) - \theta_c(K) \sim 23$ mrad

For single photons: $\delta\theta_c(\text{meas.}) = \sigma_0 \sim 14$ mrad,
typical value for a 20mm thick radiator and
6mm PMT pad size

Per track:

$$\sigma_{\text{track}} = \frac{\sigma_0}{\sqrt{N_{pe}}}$$

Separation: $[\theta_c(\pi) - \theta_c(K)] / \sigma_{\text{track}}$

$\rightarrow 5\sigma$ separation with $N_{pe} \sim 10$

Radiator with multiple refractive indices

Small number of photons from aerogel \rightarrow need a thick layer of aerogel.
How to improve the resolution by keeping the same number of photons?

\rightarrow stack two tiles with different refractive indices:
“focusing” configuration

normal

\rightarrow focusing radiator

Focusing configuration – data

4cm aerogel single index

2+2cm aerogel

→ NIM A548 (2005) 383, NIMA 565 (2006) 457

4x4 array of flat panel MAPMTs

Radiator with multiple refractive indices 2

Such a configuration is only possible with aerogel (a form of Si_xO_y) – material with a **tunable** refractive index between **1.01** and **1.07**.

Requires aerogel with high transparency

INSTR20

Detector plane covered with 2 x 124 tiles water-jet cut tiles (~ 17x17cm)

The big eye of ARICH – 420 HAPDs

Sensor: Hybrid APD - HAPD

HAPD R&D project in collaboration with HPK.

ARICH – one of the first rings and performance

Reasonable agreement with MC expectations – but still room for improvement.

PANDA Forward RICH

Focusing 2-layer aerogel configuration

Radiator configuration

- 1-st layer: $n=1.0526$, $t=2\text{cm}$
- 2-nd layer: $n=1.0500$, $t=2\text{cm}$

DiRICH FEE (GSI)

- Designed for H12700 readout
- 12x32ch preamp+disc+TDC
- 2 Gbps output link

Mirrors

- Flat
- 2 mm float glass
- Al+SiO₂ coating

Aerogel radiator

- Focusing 2- or 3-layer aerogel
- $n \approx 1.05$
- 3 x 1 m² area
- 40 mm thickness

Photon Detector

- H12700 MaPMTs (Hamamatsu), 1400 pcs
- flat panel
- 87% active/total area ratio
- 8x8 anode pixels of 6mm size

Test beam results in good agreement with MC expectations

→ Talk by S. Kononov

DIRC (@BaBar) - detector of internally reflected Cherenkov light

4 x 1.225 m Bars
 glued end-to-end

DIRC performance

← Lots of photons!

Excellent π/K separation

PANDA DIRC counters

Barrel DIRC

Goal: 3 s.d. π/K separation up to 3.5 GeV/c

Endcap Disc DIRC

Goal: 3 s.d. π/K separation up to 4 GeV/c

Magnitude of photon angles in radiator preserved

→ talk by Carsten Schwarz

PANDA Barrel DIRC

Design: based on BABAR DIRC and SuperB FDIRC with key improvements

Barrel radius ~48 cm; expansion volume depth: 30 cm.

48 narrow radiator bars, synthetic fused silica

17 mm (T) x 53 mm (W) x 2400 mm (L).

Compact photon detector:

30 cm fused silica expansion volume
8192 channels of MCP-PMTs in ~1T B field

Focusing optics: spherical lens system

Fast photon detection:

fast TDC plus TOT electronics,

→ 100-200 ps timing

→ talk by Carsten Schwarz

→ Single photon sensors: MCP PMTs, see talk by J. Va'vra

→ One more DIRC: GlueX, talk ba J. Schwiening

SiPMs as photon detectors?

SiPM is an array of APDs operating in Geiger mode. Characteristics:

- low operation voltage $\sim 10\text{-}100\text{ V}$
- gain $\sim 10^6$
- peak PDE up to 65%(@400nm)
 $\text{PDE} = \text{QE} \times \epsilon_{\text{geiger}} \times \epsilon_{\text{geo}}$ (up to 5x PMT!)
- ϵ_{geo} – dead space between the cells
- time resolution $\sim 100\text{ ps}$
- works in high magnetic field
- dark counts \sim few 100 kHz/mm²
- radiation damage (p,n)

Not trivial to use in a RICH where we have to detect single photons!

Dark counts have single photon pulse heights (rate 0.1-1 MHz per mm²)

SiPM as photosensor for a RICH counter

Improve the signal to noise ratio:

- Reduce the noise by a narrow ($<10\text{ns}$) time window (Cherenkov light is prompt!)
- Increase the number of signal hits per single sensor by using light collectors (=improve signal-to-noise ratio)

E.g. light collector with reflective walls or plastic light guide

Next step: use arrays of SiPMs

Example: Hamamatsu MPPC S11834-3388DF

- 8x8 SiPM array, with 5x5 mm² SiPM channels
- Active area 3x3 mm²

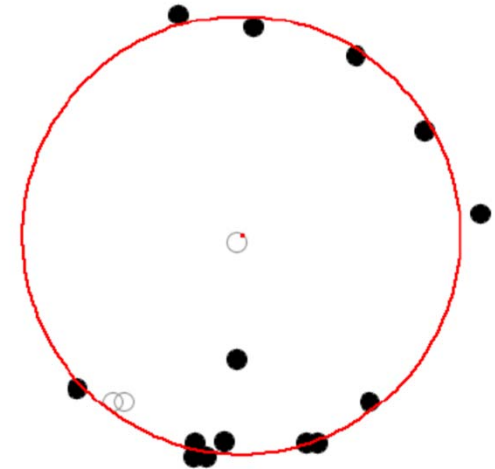

+ array of quartz light collectors

Digital SiPM

Digital SiPM (Philips): instead of an analog sum of signals from all cells of a single SiPM, use on board electronics for a digital sum + time stamp

Square matrix **20x20 cm²**

- Sensors: DPC3200-22-44
- 3x3 modules = 6x6 tiles = 24x24 dies = 48x48 pixels in total
- 576 time channels
- 2304 amplitude (position) channels
- 4 levels of FPGA readout: tiles, modules, bus boards, test board

→ A.Y. Barnyakov et al., NIM A732 (2013) 352

SiPMs: Radiation damage

Expected fluence at 50/ab at Belle II:
 $2\text{-}20 \times 10^{11} \text{ n cm}^{-2}$

→ Worst than the lowest line

Single photon sensitivity required!

- Need cooling of sensors and wave-form sampling readout electronics
- Annealing?

... and more radiation resistant SiPMs...

PID for the Electron Ion Collider

- **h-endcap**: A RICH with two radiators (gas + aerogel) is needed for π/K separation up to ~ 50 GeV/c **dRICH**
- **e-endcap**: A compact aerogel RICH which can be projective π/K separation up to ~ 10 GeV/c **mRICH**
- **barrel**: A high-performance DIRC provides a compact and cost-effective way to cover the area. π/K separation up to $\sim 6-7$ GeV/c **DIRC**

- **TOF (and/or dE/dx in TPC)**: can cover lower momenta.

Sensors:
SiPMs

→ talk by Jochen Schwiening

Wire chamber based photon detectors: recent developments

Instead of MWPC:

- Use multiple GEM with semitransparent or reflective photocathode → PHENIX RICH
- Use chambers with multiple thick GEM (THGEM) with transm. or refl. photocathode (considered for the COMPASS RICH)

Ion damage of the photocathode: ions can be blocked

Identification of charged particles

Particles (e, μ , π , K, p) in the final state are identified by their **mass** or by the **way they interact**.

Determination of **mass**: from the relation between momentum and velocity, $p = \gamma m v$ (p is known - radius of curvature in magnetic field)

→ Measure velocity by:

- time of flight
- ionisation losses dE/dx
- Cherenkov photon angle (and/or yield)
- transition radiation

Mainly used for the identification of hadrons.

Identification through **interaction**: electrons and muons

- muon systems
- calorimeters

Time-of-Flight (TOF) counters

Measure velocity by measuring the time between

- the interaction and
- the passing of the particle through the TOF counter.

Traditionally: plastic scintillator + PMTs

Typical resolution: ~ 100 ps $\rightarrow \pi/K$ separation up to ~ 1 GeV.

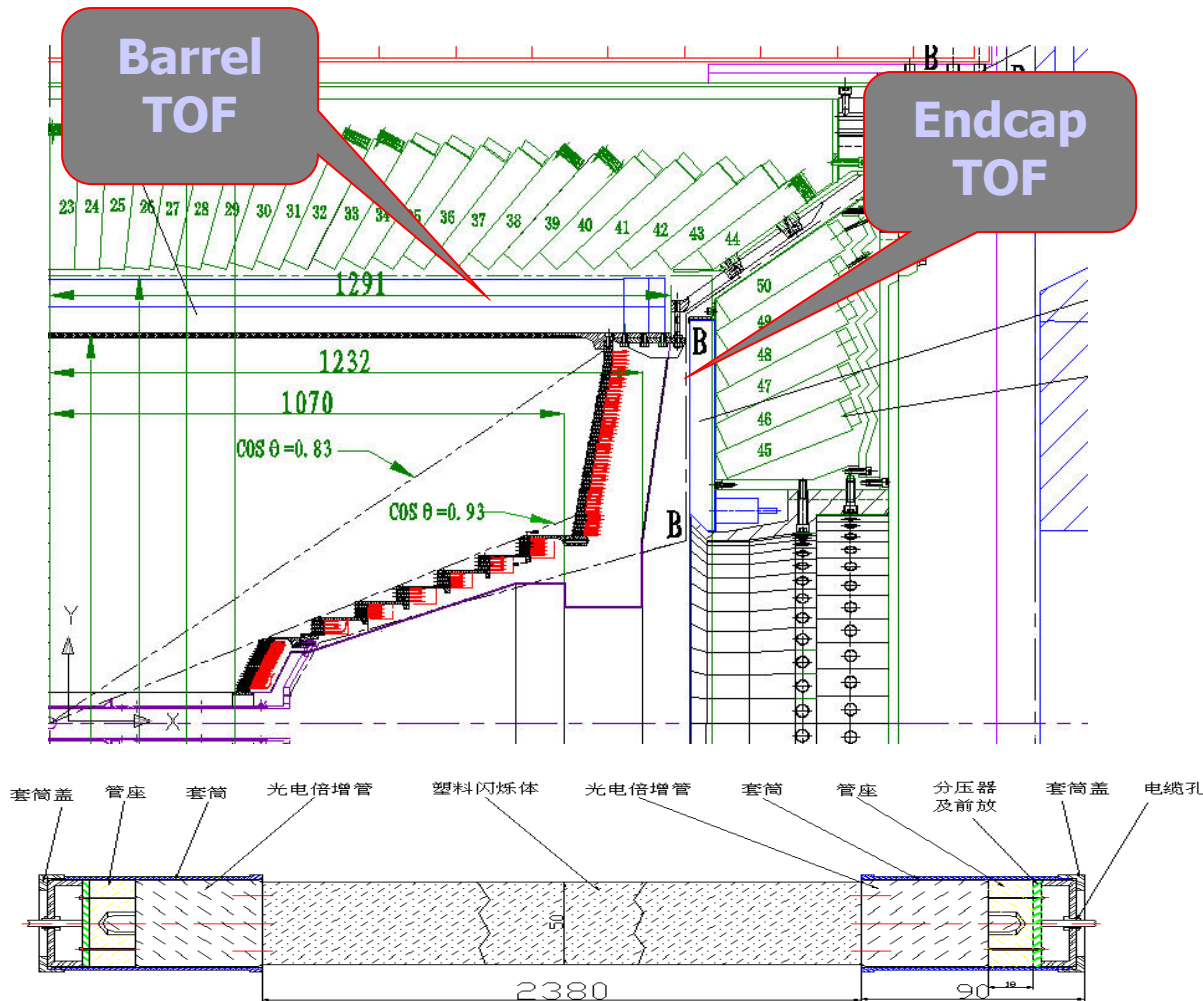

Time difference between π and K:

\rightarrow BESSIII

BESIII: Time-Of-Flight counters

Beam test results:
two TOF modules

TOF module: high quality plastic scintillator: 2.4 m long, 5cm thick, two PMTs with preamplifiers

Time-of-Flight (TOF) counters

Measure velocity by measuring the time between the interaction and the passing of the particle through the TOF counter.

Traditionally: plastic scintillator + PMTs

Typical resolution: ~ 100 ps $\rightarrow \pi/K$ separation up to ~ 1 GeV.

To go beyond that: need faster detectors:
 \rightarrow use Cherenkov light (prompt) instead of scintillations
 \rightarrow use a fast gas detector (Multi gap RPC)

However: make sure you also know the interaction time very precisely...

Time difference between π and K:

ALICE TOF

Very fast large area (140m^2) particle detector:

→ MRPC, multi-gap RPC

$\sigma = 50\text{ps}$ (incl. read-out)

π/K separation (3σ) up to $2.5\text{ GeV}/c$ at large track densities

TOF with Cherenkov light

Idea: detect Cherenkov light with a very fast photon detector (MCP PMT).

Cherenkov light is produced in a quartz plate in front of the MCP PMT and in the PMT window.

→ resolution $\sim 5\text{ps}$ measured

- K. Inami NIMA 560 (2006) 303
- J. Va'vra NIMA 595 (2008) 270

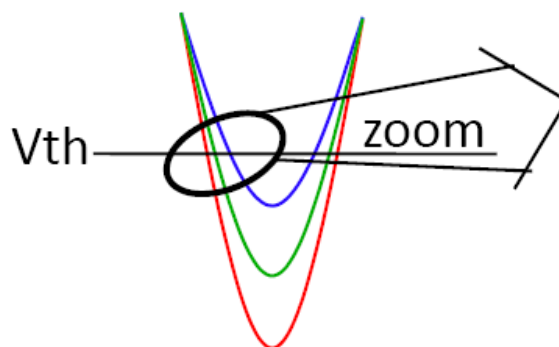

Proof of principle: beamt test with pions and protons at 2 GeV/c.

Open issues:

- read-out
- start time

Read out: for precise timing mitigate time walk

Variation of time determined with a leading edge discriminator: **smaller pulses give a delayed signal.** → Has to be corrected!

- Measure both time (TDC) and amplitude (ADC), correct time of arrival by using a $\Delta T(\text{ADC})$ correction
- Use constant fraction discriminator (CFD) →
- Wave-form sampling →

e.g. Labrador 3,
G. Varner, U Hawaii

Identification of charged particles

Particles (e, μ , π , K, p) in the final state are identified by their **mass** or by the **way they interact**.

Determination of **mass**: from the relation between momentum and velocity, $p = \gamma m v$ (p is known - radius of curvature in magnetic field)

→ Measure velocity by:

- time of flight
- ionisation losses dE/dx
- Cherenkov photon angle (and/or yield)
- transition radiation

Mainly used for the identification of hadrons.

Identification through **interaction**: electrons and muons

- muon systems
- calorimeters

Transition radiation

E.M. radiation emitted by a charged particle at the boundary of two media with different refractive indices

Emission rate depends on γ (Lorentz factor): becomes important at $\gamma \sim 1000$

- Electrons at 0.5 GeV
- Pions above 140 GeV

Emission probability per boundary $\sim \alpha = 1/137$

Emission angle $\sim 1/\gamma$

Typical photon energy: ~ 10 keV \rightarrow X rays

Transition radiation - detection

Emission probability per boundary $\sim \alpha = 1/137$

→ Need many boundaries

- Stacks of thin foils or
- Porous materials – foam with many boundaries of individual 'bubbles'

Typical photon energy: ~ 10 keV → X rays

→ Need a wire chamber with a high Z gas (Xe) in the gas mixture
(=large cross section for photoeffect of X rays)

Emission angle $\sim 1/\gamma$

→ Hits from TR photons along the charged particle direction

- Separation of X ray hits (high energy deposit on one place) against ionisation losses (spread out along the track)
- Two thresholds: lower for ionisation losses, higher for X ray detection

Transition radiation - detection

- Hits from TR photons along the charged particle direction
- Separation of X ray hits (high energy deposit on one place) against ionisation losses (spread out along the track)
- Two thresholds: lower to remove noise, higher to separate X ray conversions from ionisation by charged particles
- Small circles: between low and high threshold (ionisation)
- Big circles: high threshold (X ray detection)

(pion below the TR threshold, e above)

ATLAS Transition Radiator Tracker

Transition radiation – new aspects

Extend PID beyond $\gamma=1000$? Idea: detect TRD gamma rays in a Si pixel detector, measure angle and energy. In the study by A. Romaniouk et al. it was $480\mu\text{m}$ Si bonded to the Timepix3 chip

Maximum at:

$$\theta = \sqrt{\frac{4\pi^2 c^2 r^2}{(l_1 \omega_1^2 + l_2 \omega_2^2)(l_1 + l_2)}} - 1/\gamma^2.$$

Figure 14: Relative position of identified TR photon clusters with respect to the particle clusters for 20 GeV/c electrons crossing the polypropylene radiator. Left panel: data. Right panel: MC simulation.

Summary

Particle identification is an essential part of several experiments, and has contributed substantially to our present understanding of elementary particles and their interactions. It will continue to have an important impact in searches for new physics.

A large variety of techniques has been developed for different kinematic regions and different particles.

New concepts and detectors are being studied → this is a very active area of detector R+D.

Back-up slides

PID coverage of kaon/pion spectra in BaBar

Tagging Kaons

$B \rightarrow \pi\pi$

$B \rightarrow DK$

Photon detection efficiency

Quantum efficiency

Number of detected photons

Example: in 1m of air ($n=1.00027$) a track with $\beta=1$ emits **$N=41$ photons** in the spectral range of visible light ($\Delta E \sim 2$ eV).

If Čerenkov photons were detected with an average detection efficiency of $\varepsilon=0.1$ over this interval, **$N=4$ photons** would be measured.

Few photons detected

→ Important to have a **low noise** detector

Measuring the Cherenkov angle

Tracking system (measures the direction of the particle)

Tracking system tells us where the particle hit the radiator, and at which angle.

Use this information to calculate the **Cherenkov angle** for each individual detected photon

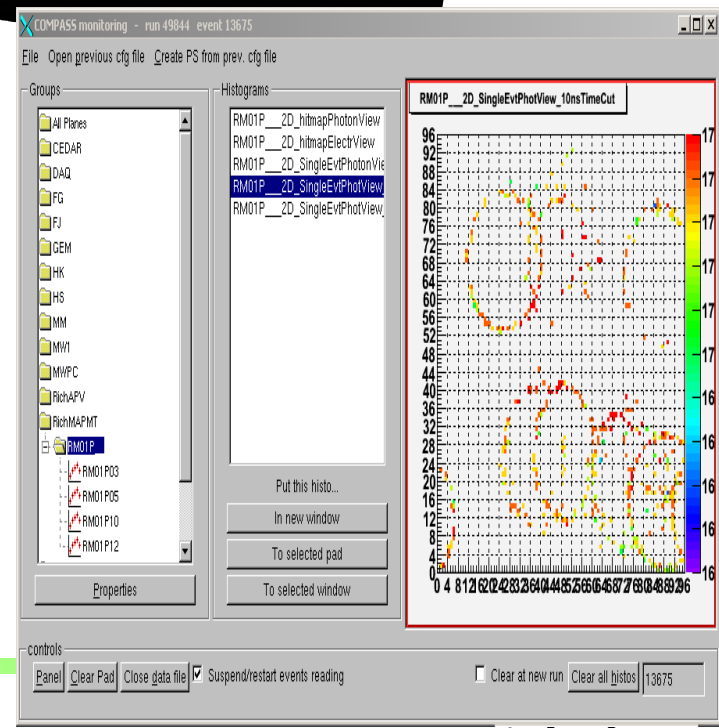

Photon detector for the COMPASS RICH-1

Upgraded COMPASS RICH-1:
similar concept as in the
HERA-B RICH

New features:

- UV extended PMTs & lenses (down to 200 nm) → more photons
- surface ratio = (telescope entrance surface) / (photocathode surface) = 7
- fast electronics with <120 ps time resolution

HADES Upgrade

- Replace CsI-MWPCs with MaPMTs
 - Hamamatsu H12700
 - Same as for CBM-RICH
 - Also share electronics

Mirror alignment

Gas radiator RICHes: large mirrors \rightarrow tens of segments \rightarrow need relative alignment

- Spherical mirror: 80 hexagonal segments
- Planar mirrors: 2x18 rectangular segments

Aligning pairs of spherical and planar segments.

Misalignment: Cherenkov angle depends on the azimuthal angle around the track

Mirror alignment

Misalignment: Cherenkov angle depends on the azimuthal angle around the track

Use unambiguous photons.

mirrors 34 14

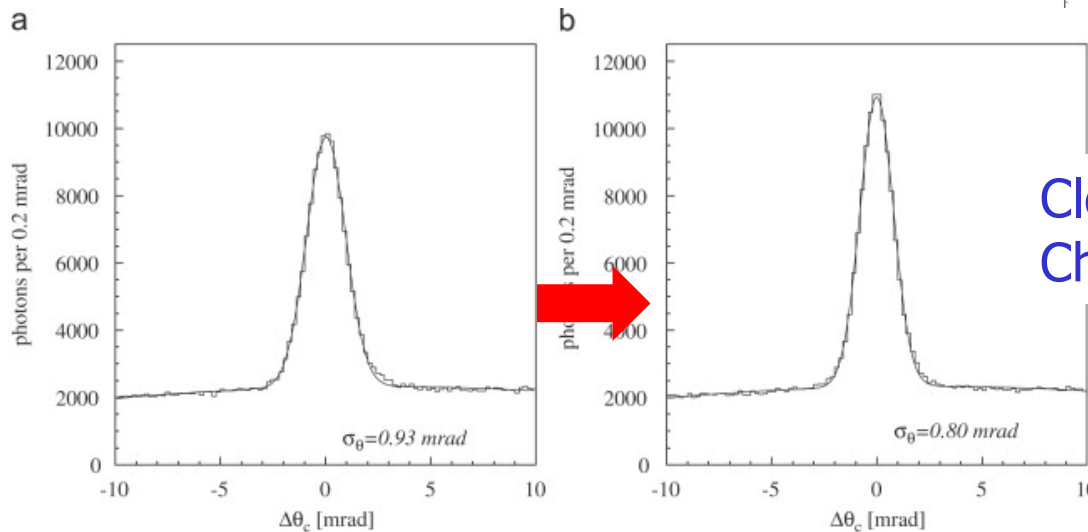

Slice in ϕ_c

Mirror alignment

Initial mirror system alignment:
with optical methods, theodolite.

Alignment with data: tells you the
ultimate truth...

Combine all alignment data for all
(possible) pairs of segments →
solve a system of linear equations

Clear improvement in
Cherenkov angle resolution

TOP R+D areas

- Very fast photosensors for operation in 1.5 T field (MCP PMTs)
- R+D to mitigate aging of photocathodes in MCP PMTs (ALD)

- Very fast and compact readout electronics with waveform sampling for a precise time measurement →
- Production of large quartz pieces, construction of modules, mechanics and installation methods
- Analytic expressions for the very complex 2D likelihood functions.

ARICH photo sensor: HAPD

- **HAPD – Hybrid Avalanche Photo-Detector**

Size	73x73 mm
# of channels	144 (36-ch APDx4)
Total gain	>60000 (1500 x 40)
Peak QE	~30%
Active area	64%
Weight	220g

- 420 modules to cover the detector plane

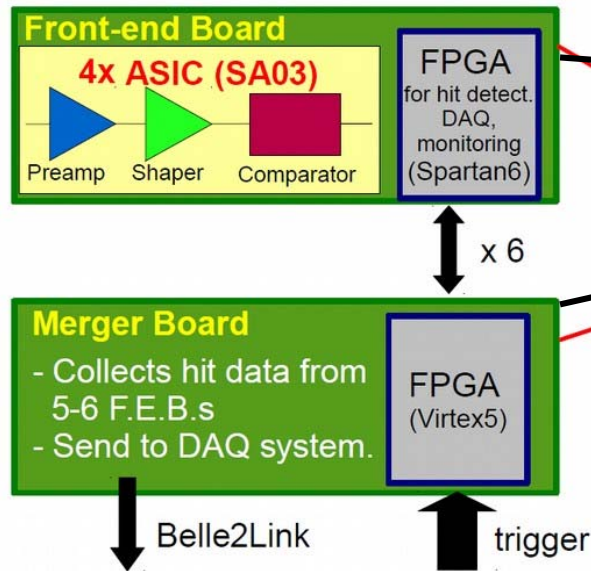

Feb. 2;

TECEP KIZAN, Ljubljana

ARICH read-out electronics

- In total ~60k channels
- Limited space of 5cm behind HAPDs

- Variable gain (3.1-12.5 V/pC),
shaping time (100-200 ns)
→ optimization for
increased noise levels

MCP PMT: processes involved in photon detection

Parameters used:

- $U = 200 \text{ V}$
- $l = 6 \text{ mm (K-MCP)}$
- $E_0 = 1 \text{ eV}$
- $m_e = 511 \text{ keV}/c^2$
- $e_0 = 1.6 \cdot 10^{-19} \text{ As}$

Internal-reflection

Photo-electron:

- $d_{0,\max} \sim 0.8 \text{ mm}$
- $t_0 \sim 1.4 \text{ ns}$
- $\Delta t_0 \sim 100 \text{ ps}$

Backscattering:

- $d_{1,\max} \sim 12 \text{ mm}$
- $t_{1,\max} \sim 2.8 \text{ ns}$

Charge sharing

MCP PMT timing

Tails understood (scattering of photoelectrons off the MCP), can be significantly reduced by:

- decreased photocathode-MCP distance and
- increased voltage difference

- prompt signal ~ 70%
- short delay ~ 20%
- ~ 10% uniform distribution

MCP PMT: sensitivity

Number of detected hits on individual channels as a function of light spot position.

$B = 0 \text{ T}$,
 $HV = 2400 \text{ V}$

$B = 1.5 \text{ T}$,
 $HV = 2500 \text{ V}$

In the presence of magnetic field, charge sharing and cross talk due to long range photoelectron back-scattering are considerably reduced.

Time resolution: blue vs red

	E407	S137	H100C	H050C	H025C
σ_{red} (ps)	127	182	145	212	154
σ_{blue} (ps)	97	151	136	358	135

• $\sigma \approx 100$ ps

• $\sigma_{\text{red}} > \sigma_{\text{blue}}$

Photon detector with SiPMs and light guides

Radiation damage

Expected fluence at 50/ab at
Belle II: $2-20 \cdot 10^{11} \text{ n cm}^{-2}$
→ Worst than the lowest line

→ Very hard to use present SiPMs as single photon detectors in Belle II because of radiation damage by neutrons

→ Also: could only be used with a sophisticated electronics – wave-form sampling

First generation of RICH counters

DELPHI, SLD, OMEGA RICH counters: all employed wire chamber based photon detectors (UV photon \rightarrow photo-electron \rightarrow detection of a single electron in a TPC)

Photosensitive component:
TMAE added to the gas mixture

Fast RICH counters with wire chambers

Multiwire chamber with
cathode pad read-out:
→ short drift distances,
fast detector

Photosensitive component:

- in the gas mixture (**TEA**):
CLEOIII RICH
- or a layer on one of the cathodes
(**CsI** on the printed circuit cathode
with pads) HADES, COMPASS,
ALICE

Works in high magnetic field!

CERN CsI deposition plant

Photocathode produced with a well defined, several step procedure, with CsI vacuum deposition and subsequent heat conditioning

Thickness monitor

PC

4 CsI sources + shutters

Remote controlled enclosure box

ALICE RICH = HMPID

The largest scale (11 m²) application of CsI photo-cathodes in HEP!

Six photo-cathodes per module

CsI photo-cathode is segmented in **0.8x0.84 cm pads**

Transition radiation detectors

Example:

Radiator: organic foam
between the detector
tubes (straws made of
capton foil)

Performance: pion efficiency (fake prob.)
vs electron efficiency

Transition radiation detectors - performance

Performance: pion efficiency (fake prob.) vs detector length

ATLAS TRT

Radiator: 3mm thick layers made of polypropylene-polyethylene fibers with ~ 19 micron diameter, density: 0.06 g/cm^3

Straw tubes: 4mm diameter with 31 micron diameter anode wires, gas: 70% Xe, 27% CO₂, 3% O₂.

TRT module

TRT: pion-electron separation

π fake probability at 90% e efficiency

Identification of charged particles

Particles (e, μ , π , K, p) in the final state are identified by their **mass** or by the **way they interact**.

Determination of **mass**: from the relation between momentum and velocity, $p = \gamma m v$ (p is known - radius of curvature in magnetic field)

→ Measure velocity by:

- time of flight
- ionisation losses dE/dx
- Cherenkov photon angle (and/or yield)
- transition radiation

Mainly used for the identification of hadrons.

Identification through **interaction**: electrons and muons

- muon systems
- calorimeters

Identification with the dE/dx measurement

dE/dx is a function of velocity β
 For particles with different mass the
 Bethe-Bloch curve gets displaced
 if plotted as a function of p

For good separation: resolution should be $\sim 5\%$

Measure in each drift chamber layer – use truncated mean

Identification with dE/dx measurement

Problem: long tails (not Gaussian!)

Energy loss distribution for particles with $\beta\gamma=3.6$ traversing 1.2 cm of Ar gas (solid line).

Parameters describing $f(\Delta)$ are

$\Delta_p(x; \beta\gamma)$: the most probable energy loss = the position of the maximum at 1371 eV, and

W : the full-width-at-half-maximum (FWHM) of 1463 eV. The mean energy loss is 3044 eV.

Dotted line: the original Landau function.

→ Many samples along the track (~ 100 in ALICE TPC), remove the largest $\sim 40\%$ values (reduce the influence of the long tail) → truncated mean

→ Hans Bichsel: A method to improve tracking and particle identification in TPCs and silicon detectors, NIM A562 (2006) 154

Identification with dE/dx measurement

dE/dx performance in the STAR TPC

gold-gold
collisions

Energy loss in the STAR TPC: truncated mean as a function of momentum. The curves are Bichsel model predictions.

dE/dx in ALICE

TPC dE/dx

relativistic rise region

Photon detector

Requirements:

- few mm spatial resolution
- ~100 ps timing resolution

Bar-box:

8 MCP-PMT, 512 pixels (total 8 k readout channels) with pixel size 6 x 6 mm² work in 1T magnetic field survive 10 years of PANDA (aging)

Most sensors with ALD coated MCPs have lifetime > 5 C/cm²
